**H. COLLIER & SONS, LTD.,
PLUMSTEAD, S.E.18.**

ON the firm foundation of intrinsic worth and proved efficiency the world-wide reputation of Sphinx Plugs has been built.

It is their absolute reliability which motor cyclists so much appreciate. If you, too, would enhance the pleasure of your motoring, fit "Sphinx" — England's most Durable Plugs.

THE SPHINX MFG. CO., BIRMINGHAM

The BRITISH "EXCELSIOR"

Motor Cycles.

British Excelsior Motor Cycles are built for long service, and to give that service at the lowest cost. Being of robust construction, equipped with engines of the highest repute, they give no trouble. Upkeep costs are negligible. You may pay more for a motor cycle but you cannot buy better value. The new models are as follow:

8 h.p. Twin "J.A.P." with three-speed countershaft gear; all chain transmission with totally enclosed chains; instantly detachable interchangeable wheels, including sidecar wheel; rear brake of the internal expanding band pattern, the adjustment of which will not in any way be interfered with when detaching the wheel, which remarks also apply to the transmission. 28 x 3 in. wheels fitted with Dunlop heavy tyres. Druid Mark II. pattern fork, etc., etc.

6 h.p. Twin "J.A.P." to similar specification, and **2½ h.p.** Two-stroke with "Villiers" power unit and countershaft gear.

Bayliss, Thomas & Co., Excelsior Works, **Coventry.**

(PATENT)

TERRY'S PATENT SPRING LINK.

Replaces fixed link. Absorbs bar vibration. Gives motor cycling a luxury it never had before. Ask for Leaflet "Tests and Trials," and form for measurements.

**544A.—SET OF FIVE THIN WELL-TEMPERED STEEL SPANNERS.**

.095 and .125 thick. Grip range $\frac{1}{16}$ in. to $\frac{1}{2}$ in. Whit., and $\frac{1}{16}$ in. across flats. Oxidised, 5/-; plated, 6/- set.

From your Agent please.

PATENT NO 20337.

678A.—MOTOR CYCLE VALVE SPRING LIFTER.

Fits any engine. Holds valve down, spring clear of pin, leaves both hands free. Enables you to take engine down while hot. 2/- each.

From your Agent

TERRY AND RECONSTRUCTION.

EVERY effort must tell now. Everything that tends to better service and efficiency must be the basis of equipment. Terry time and labour savers have always been in demand, and our work in the task of Reconstruction is proceeding as rapidly as possible. We are planning for early supplies, to meet the needs that will arise when "Dora" shall be but a memory. Meanwhile, we urge the placing of orders with agents, so that we may meet their needs as quickly as convenient, and may 1919 usher in the millennium of peace and happiness.

HERBERT TERRY & SONS, LTD., The Spring and Presswork Specialists, REDDITCH, England.

687.—Best quality hardened and tempered **KICK-UP STAND CLIP.**
2/- each.

From your Agent.

**785.—TERRY'S PATENT "PERFECT" BELT FASTENER.**

Hook ends are pressed from solid STEEL, centre piece has no joints. Has immense strength, and ease of detachability. For all belts. With extra link, 1/- each.

From your own Agent.

Always ask for a **TERRY WASHER.** Accurately made in high-grade STEEL, they have resiliency without set, and toughness without brittleness.

Order supplies from your own Agent.

**735.—TERRY'S "ELECTRIC" TYRE LEVER SET.**

Best quality steel. Motor cycle size. 1/6 per set.

From your own Agent.

**692.—INFLATOR CLIPS.**

Useful for fixing to exhaust pipe to hold plug for testing spark

6d. per pair.

TERRY'S HIGH-GRADE SPRINGS for all purposes render satisfactory service, and for Valve Springs our "Ex" quality is recommended.

Your orders should be given to your Agent.

PATENT APPLIED FOR & REGISTERED

TRACING TROUBLES

MOTOR CYCLE FAULTS, THEIR IDENTIFICATION AND
THEIR REMEDIES SIMPLY AND FULLY EXPLAINED

Third Edition (Second Reprint).

In this edition considerable changes
have been made, all obsolete matter
has been taken out and new material
has been added to bring it up to date.

The section which deals with the
two-stroke type of motor cycle has
been enlarged and re-arranged in
view of the vastly increased number
of two-stroke engines now in use.

A new section dealing with electric
lighting dynamos as applied to motor
cycles has been added.

The Book that helps Motor Cyclists out of their Troubles.

¶ All motor cycle riders, and
especially those using their
machines for vital work, should
keep a copy of this little volume
handy. It will help them out of
many a difficulty.

¶ Not only does it show how to
locate a fault quickly, but also
provides a remedy for it when it
has been found. All conceivable
motor cycle failures are dealt
with by the author.

Reconstruction and Overseas Trade.

THE whole of this issue is the expression of our faith in the future of the motor cycle, and not our faith alone, but that of the trade and the riding public. Let it not be imagined, however, that a successful future can lie before the most sporting of all mechanically propelled vehicles without great and very special effort on the part of all concerned.

In the past it was, we fear, the habit of many manufacturers to look upon the British Isles only as their market, and to regard our Overseas Dominions and foreign countries simply in the light of places where some of their surplus stock might find purchasers. This attitude will not make for success in the future. The manufacturer should regard the whole world as his market, but chiefly, of course, should he look to the British Empire, by which we mean the Empire as a whole—i.e., the federation of free states which make up the British Dominions. Now we are convinced that a really successful foreign trade cannot be built up by the methods which have hitherto been employed. Special machines must be designed which are really suitable for the conditions obtaining in the newer and less fully developed countries. In designing these machines the opinions of residents in the outlying parts of the world should be consulted far more than has hitherto been the case. The British motor cycle is a very fine mount, entirely suitable for use in this and many other countries, but when the needs of those who live at "the back of beyond," as it were, come to be considered, it will be found that the British machine—excellent as it is for those purposes for which it was designed—will fall short of perfection, even when provided with heavier rims and spokes, larger tyres, and slightly more ground clearance, which items represent the usual alterations in the standard machine to convert it into an Overseas model. This should be designed from beginning to end with the

object of making it capable of overcoming the obstacles that it will have to face, and of satisfying the requirements of those who will ride it.

These remarks must suffice for the present regarding the machines themselves, but a few words respecting the selling methods will not be out of place. These, in our opinion, at once require very thorough revision. During the war the American manufacturers made very great headway not only in foreign countries but in our own Colonies. This was, of course, only to be expected in view of the abnormal conditions which prevailed, and the fact that America did not come into the war for so long a time after the commencement of hostilities. The British manufacturer, therefore, has much ground to recover, and we fear that he will never recover it till he has improved his methods out of all recognition. Let him study the American methods and improve upon them. At present the American is able to offer to British colonists better terms, better service in the vital matter of spares, and a machine which in many respects is more suited to his requirements than the British article; and so long as this is so the British manufacturer will have to take second place. Let him not despair, however, but set to work on the right lines either by forming depots in every dominion for the proper distribution of his machines and spares, or by appointing suitable agents and equipping them in such a way that they may be able to supply sub-agents in the different districts with adequate stocks. Prices, too, must be settled on equitable lines, and not left to the caprice of the smaller dealers. There are hundreds, nay thousands, of men in our Overseas Dominions who from a patriotic feeling alone would buy the British article in preference to any other, provided that they were assured the maker would continue to take a real interest in their machines, and that they could purchase spares without having to send to England and waiting many months for their delivery.

THE MAKERS' VIEWS.

Comments on the Opinions which appear in this Issue.

THE problems before manufacturers during the "reconstruction" period are many; that they are fully appreciated by most of the makers of motor cycles is revealed in their contributions appearing in this issue. The altered conditions pertaining to the cost of labour undoubtedly will be one of the most important factors which the industry will have to face, and although all of our captains of industry do not refer to this, we have evidence that all are thinking about it.

Prices and Tariffs.

Mr. W. Douglas goes into figures, both in connection with labour and material. Wages, he writes, are 100% to 300% higher than in 1914, and with material increased in price 100% to 600%. He points out that the improved shop methods cannot be expected to counterbalance the increases.

Mr. J. W. Stocks, of Ariel Motors, Ltd., also touches upon this subject, but he thinks that foreign competition may "straighten out matters." Mr. Stocks also favours a reciprocal tariff, a view shared with Mr. Harold Bowden, of the Raleigh Co., who suggests an import duty of at least 33% in order to protect the British motor cycle industry during the period of reconstruction. Mr. Humphries, of the O.K. firm, states that this protection should be in exactly the same ratio as the American tariff wall against ourselves.

Mr. Frank E. Baker, of Precision engine fame, gives a commonsense view of the Ford motor cycle proposition, and as this gentleman has had American experience, and is in close touch with American methods, his short contribution is of more than ordinary interest. Mr. Baker also pays tribute to the work of *The Motor Cycle* in the pioneer days and during the war.

Several of our contributors have dealt with the post-war motor cycle. Mr. Hyde, of the B.S.A., thinks that the single will retain its popularity, if only on account of its good work in the war, but he appreciates that there will be a brisk demand for a 6 h.p. V twin for sidecar work. Mr. R. W. Smith, the Enfield managing director, thinks that the best way to meet demand during the immediate reconstruction period will be to reintroduce existing models so that there will

be the least delay in delivery. Mr. J. W. Stocks shares this view, as does Mr. Norman T. Downes, of the New Imperial Co., but Mr. W. H. Carson (Excelsior Motor Co., Ltd.) thinks that very few makers will be satisfied to recommence where they left off in 1914.

In the future, concentration upon few models is likely to be the rule instead of the exception. Mr. Geo. Stevens, of the A.J.S. firm, mentions the necessity of concentration on one model and of quantity production, and for a more scientific knowledge of metals, while Mr. Rigby (Royal Ruby) and Mr. N. Downes refer to concentration.

Mr. Morgan writes of cycle cars and mentions that in all probability the demand in 1919 will exceed the supply, while Mr. Butterfield appears to think the word "reconstruction," in connection with motor cycles, conveys an impression that the industry has been reduced to a state far worse than is really the case.

Mr. C. A. Hyde, President of the Cycle and Motor Cycle Manufacturers' and Traders' Union, refers at length to the disposal of war-worn motor cycles supplied to the Allied Governments. Mr. Hyde deals with the question from both makers' and riders' points of view.

Mr. H. A. Collier makes a plea for greater intercourse and co-operation within the industry to meet international competition in Overseas markets, while Mr. P. F. Bennett, chairman of the British Ignition Apparatus Association, gives some

particulars concerning Great Britain's latest industry in which the value of such co-operation is made manifest.

The Benefit to the Rider.

Mr. Hulbert, of the Triumph Co., still pins his faith to the reliable single-cylinder machine, and is reminiscent concerning the days of long ago, while Mr. W. J. Lloyd (L.M.C.) makes an interesting announcement anent his post-war spring frame design.

Altogether, from the views expressed, we think that readers of *The Motor Cycle* will appreciate that the captains of the industry are fully alive to the possibilities of the future, and that the experience gained in the making of munitions will eventually benefit the riding public.

RIDER AND MAKER.

LIXION

Easy Starting.

IN pre-war days the motor bicycle did not enjoy too good a reputation for easy starting, so far as the general public were concerned. Our good starts attracted no attention, but a rider who spent ten minutes on pedalling kicks, with an accompaniment of oaths and backfires, set people thinking and talking. Still there was a substratum of fact in the popular impression that starting was anxious work. New machines almost invariably started with consummate ease. But the induction system was not always airtight after an overhaul. The somewhat crude lubrications fitted to many mounts tempted anxious owners to soil their plugs. The magneto often lost its youthful zip after a few months: one of our staff used to own a machine which would not start on the handle unless its contact breaker points were washed over with petrol, and most contact breaker arms grew sluggish in wet weather. In other words, the machine sooner or later degenerated into an uncertain starter unless its owner was a bit of a mechanic.

Starting the 1920 'Bus.

NOTHING creates a worse impression on the nibbling purchaser or on an observant public than the spectacle of an ignorant and perspiring individual foaming oaths over a quiescent motor cycle. If our fears about the quality of post-war spirit materialise, heavy fuel is going to import a fresh difficulty. It is therefore up to the trade to eliminate every possible difficulty; and all the troubles indicated in the previous paragraph can be cured by sound design. It is bad design to supply an induction pipe which can only be reassembled in airtight condition by using fat bandages of insulating tape. It is bad design to supply an engine which can be grossly over-oiled by anybody but a fool, and worse design which causes an engine to "cluck" like a cheap jelly if a stupid owner injects a gill too much oil. Long plain bearings, tight-fitting pistons with four rings, and fly-wheels with invisible crank case clearance are so many requests for starting troubles. A magneto contact breaker should be proof against over lubrication, and should have a rocker arm which cannot stick. These elementary reforms are a prefacé to the main question, which is how to force heavy petrol to furnish a good starting mixture on a cold day. This latter problem may ultimately be solved in one of three ways:

- (a.) An unexpected supply of more volatile fuel.
- (b.) Application of heat to the carburetter.
- (c.) Mechanical atomisation of the starting charge, e.g., by a "dope spray."

Until the air leak, over-oiling, and "dud mag." factors are cleared out of the way, inexperienced riders will put all the blame on petrol; and we may get

saddled with tiresome gadgets, such as electric carburetter heaters, the necessity for which remains to be proved.

Life's Little Worries.

I AM just readying my pre-war 'bus for its first post-war jaunt, and it teaches me how patient I used to be. In the preliminary inspection I struck many irritating little jobs, all of which could have been avoided by a little care on the part of the designers concerned. The inflator connection was so tight a fit in the tyre pump handle that I had to use pliers to get it out. The tool roll needed a great deal of coaxing to fit one of the pannier tool bags, and the big wrench had to go in the opposite bag. The tyre repair outfit had to go in my pocket, as it was too wide for the pannier. If I took a smaller size of tyre outfit, it would go into the pannier, but banished the big spanner. No sane provision of any kind had been made for the small oddments, such as chain links. The only possible procedure was to mass the tyre kit, spare plugs, and valves at one end of a pannier, wrap all small oddments in rag, and wedge the whole caboodle together with more rag. Next the tyre wanted a few pounds of pressure, and the valve was so wedged in by wheel spokes and belt rim spokes that it reminded me of the old shorthorn Farman aeroplane: this 'bus is said to be properly rigged when a canary cannot get out of it! Then I tried to replenish the oil tank, and made a selection between three alternatives, viz.:

- (a.) To slop oil down the tank side.
- (b.) To remove the handle-bar.
- (c.) To remove the acetylene generator.

Finally, I took the backlash out of the throttle wire by extending the Bowden casing with a wrapping of thin wire, no adjuster being fitted: and adjusted the clutch by improvising some packing washers, as the solitary nut could not be locked, and its thread was apparently Esquimaux gas thread, or some other outlandish pitch.

Water-cooled Motor Bicycles.

ONE or two readers have asked me to put in a word for the water-cooled engine, chiefly on the ground that the extra cooling enables a more efficient engine to be adopted. From my own standpoint water-cooling has one advantage, and one only. It would enable the engine and subsidiary fittings to be so completely boxed in that the power unit could be washed down with a powerful hose. Apart from ease of cleaning, I have no wish to see a water-cooled motor cycle. The Scott does not go half as far in the direction of a streamlined case as is possible: but it certainly adds to many other merits the distinction of being the easiest machine on the road to clean.

OPINIONS

Notes on
The Past,
The Present;
and
The Future.
By Prominent
Men in the
Motor Cycle
Movement.

First Series:
Comments of the
Captains of the
Motor Cycle
Industry.
Next week
Further
Opinions will
be given.

From Mr. C. A. Hyde, of the B.S.A. Co.,
President of the Cycle and Motor
Cycle Manufacturers' and Traders'
Union.

It is difficult at this stage to forecast with any accuracy what trend the post-war demand for motor bicycles will take, but judging from Government specifications during the war, and reports from the various Fronts, the single-cylinder type has found added favour as a "no trouble" mount—easy to tune up, to adjust, and to drive, almost immune from minor ailments, and with plenty of power for all general purposes.

This favourable bias on the part of military motor cyclists cannot fail to have its effect on the post-war demand.

At the same time, however, it is anticipated that there will be a brisk demand among those desiring a higher powered mount—for a V type twin-cylinder machine of, say, about 6 h.p.—and a good deal of experimenting is going on among manufacturers with a view to perfecting this class of motor cycle.

Mr. C. A. Hyde.

An important question that must seriously be faced by those manufacturers who have supplied motor cycles to the British and Allied Governments is that of the disposal of surplus machines and spares no longer required by the authorities. To dump large numbers of such machines on the market and sell indiscriminately by auction would, probably, not only seriously affect the commercial and manufacturing arrangements of the manufacturers—which would ultimately be to the prejudice of the whole industry and sport—but private purchasers of discarded machines would, naturally, in nearly every case, run very considerable risks of finding themselves with defective mounts (for of course no warranty

would be given). At the same time, the original manufacturers would very probably be—obviously quite unfairly—blamed for defects developed as a result of abnormal stresses or careless handling at the Front, for which they would actually themselves be in no way responsible.

It has therefore been suggested that the Ministry be approached with a view to arrangements being made for all surplus motor cycles to be sold back to their respective manufacturers at an agreed price, the manufacturers then thoroughly to overhaul them, make good everything necessary, and sell to the motor cycling public as renovated machines.

Everything points to a large increase in the number of those interested in motor cycling, and manufacturers as a whole will have well learned the lessons of the war in regard to quantity production. It is doubtful, however, if any appreciable fall in prices can be expected for some time to come, since production costs will continue to rule very heavily, due to increased price of raw materials and the fact that, while wages are higher than ever they were before the war—and are likely to remain high—hours of labour are to be fewer.

From H. A. Collier (H. Collier and Sons, Ltd., Makers of the Matchless Motor Cycle).

ONE of the greatest lessons of the war has been the value of co-operation.

In the automobile industry the conditions prevailing during the war have resulted in intercourse between staffs of firms hitherto regarded as rivals, which would have been impossible under normal conditions. If this intercourse and co-operation within the industry can become permanent, it can only have a beneficial influence to the interests of manufacturers and consumers alike. It would also greatly help the industry to meet international competition in Overseas markets; this tends towards the lowering of prices, which only a large market can assure.

As in the industry, so in the pastime, should all co-operate for the advancement of the movement, and I look upon it as the duty of every motor cyclist to join

the A.C.U., and so give that body added power to promote the interests of motor cyclists.

Personally, I am looking forward to the resumption of motor cycling and the meeting of old friends with the liveliest anticipations, and shall appreciate its pleasures all the more for the forced abandonment of them during the last four years.

From Mr. Frank E. Baker, of Precision Engine Fame.

REPLYING to the Editor's enquiry as to my views on machines, methods, and general problems as they affect the motor cycling world during the reconstruction period, I would submit that in a general way these questions can be answered by the word "faith."

There was a period in the history of the motor cycling movement and trade when this attitude was even more difficult than at present. I think it would be about 1904 and 1905 when most people had given up the struggle of producing a commercial machine. It will always redound to the credit of the proprietors of *The Motor Cycle*, the Triumph Co., and of my friend Mr. Prestwich, that they held on to their belief in the ultimate success of the motor cycle.

I am looking forward to a revival of this faith in the motor bicycle, by which I mean a solo machine which affords its owner the speed and distance capacity of the automobile with the handiness, individuality, and sporting character of the bicycle. Many machines met these requirements even before the war, and their utility has been further demonstrated by our despatch riders with the various armies.

Mr. Frank E. Baker.

Opinions.—

I do not at this juncture attach any importance or magic to the word "standardisation." The motor bicycle is not yet a stereotyped production.

I hope to see a change of view on the part of the politicians and publicists generally in regard to the belief that businesses can only be economically conducted by large units of production.

The progress of the motor cycle, as of other branches of the engineering trade, is largely due to the initiative of pioneers and small concerns.

The standard motor bicycle will materialise, as in the case of the Ford car, when the genius of a particular designer, in conjunction with the necessary organising ability, provides the article.

In a communication of this kind, in which the writer is expressing his own views as to immediate possibilities, it is desirable that he should recognise that his own interests affect his outlook. I do not therefore propose to touch controversially on the merits of various types of engines.

I hope that I and my associates have contributed something that will help to broaden the use of the motor cycle and solve some of the problems of the past. Whether we are right or not can only be demonstrated by the "Man on the Road."

The future is full of hope, and competition will be keen and interesting. In the motor cycle trade, such competition, as in the past, will, I believe, be relieved of much of its dull and sordid side by the sporting spirit of the men engaged in the industry.

I take this opportunity of paying a personal tribute to the courage and enterprise that have characterised *The Motor Cycle*, to which both rider and manufacturer are incalculably indebted.

From Mr. Wm. Hughes Butterfield, A.M.I.A.E., of Butterfields, Ltd., Makers of the Levis Motor Cycle.

"RECONSTRUCTION."—It sounds rather like admitting that we were reduced to a state far worse than is really the case. There is no doubt that the past four years have shown us how necessary it is to "put our house in order," and I am of the opinion that the cessation of hostilities has found some of the motor cycle manufacturers in a state of unpreparedness.

Mr. Wm. Hughes Butterfield.

Let us appreciate the task we have before us, and let us appreciate the huge possibilities open to the motor cycle both at home and abroad.

Let us "open the throttle" and get "all out" on Production.

From Mr. W. Douglas, Head of the Firm of Douglas Motors, Ltd.

WE are mostly interested at the moment in the new industrial life and the industries generally, but particularly the motor cycle industry. The demand for motor cycles even at the present unsettled moment is enormous. What it will be when we have fully realised that victory is ours and the peace for which our fine fellows have bravely fought is an established fact, when the creation of a new working class is recognised, when the longer hours of recreation that this new life will give them are appreciated, when we are freed from the fetters of war-time legislation, what the demand will then be few of us realise. We, of Douglas Motors, are in the enviable position of having remained to a considerable extent at our normal trade, that of making motor cycles—motor cycles for the Allied armies of the world. Now we are prepared (subject to the consent of the Ministry of Munitions, which cannot be withheld very much longer under the existing circumstances) to devote our entire resources to the demands of our old clients and the riding public generally. For this we are very thankful; thankful for those who have fought our fight, and we hope that early in the New Year we may help them once more to enjoy the unparalleled pleasures of the highways of Blighty.

Much has been said during the past about the production of a low-priced motor cycle, and we fear many believed that with the advent of peace such a machine would be available.

Unfortunately many writers, whose sole experience of works costs and production consists of visions that pass in their slumbers, have created the impression that the manufacturing of a cheap motor cycle was not only a small problem, but one that many firms had solved, and that the long-looked-for present period would see the market flooded with such models. To-day we have peace with us, but what do we find? Prices greatly increasing and the entire absence of a cheap machine. With the present unsettled state of the material and labour markets this is only to be expected. High wages—100% to 300% increase over 1914—are the order of the day, and similarly materials have increased in price from 100% to 600%. Now, even with what we may have learned in shop methods during the war, the resultant higher production cannot counterbalance these increases. No concern could be more anxious than we are to give the public a cheaper machine, but no firm is more determined than we are to see that we only make an *honest machine*—a machine which, though perhaps slightly higher in price, is considerably better value than any model we have previously produced.

Mr. W. Douglas.

From Mr. E. H. Humphries, Director of Humphries and Dawes, Ltd., Makers of the O.K. Motor Cycles.

THE first and foremost feature that interests a British manufacturer to-day is what protection the British industry is going to receive at the hands of the Government.

Certain it is that, as in the instance of America, whose manufacturers have not broken down on the manufacture of their ordinary lines, and whose stocks, though low, must be considerable when taken into account with the amount of stock held by British manufacturers, protection must be afforded.

In my estimation, such protection should be in exactly the same ratio as the American tariff wall against ourselves.

The next problem is one of raw material. No indication has yet been given by the Government as to whether raw material is to be rationed or not, and since certain Government Departments are asking firms to take over surplus Government stocks, if of use to them, it does not look as though there will be a rationing scheme, but that those firms who have continued on work on motor cycles and cycles will have the advantage of whatever stocks they may be holding at the minute in their possession, although such material may be the property of the Government.

My idea of the utility motor cycle for the future will be a handy lightweight with a three-speed gear, kick starter, electrically equipped, and, provided engine ground clearance can be kept at 7in. or above, 26in. wheels will form a far more comfortable vehicle than one with 28in. wheels.

It is our intention to fit to our post-war lightweight 26in. x 3in. tyres, and undoubtedly spring frames will be a very attractive proposition.

It will be the policy of my house in future to make everything possible within its own four walls, and we are rapidly organising to this end.

From R. W. Smith, Managing Director of the Enfield Cycle Co., Ltd.

I THINK the immediate duty of the motor cycle manufacturers is to meet the existing great demand for motor cycles. For some little time output will be largely regulated by the raw material available; but, by proper utilisation of this, there should be reasonable supplies of motor cycles during the next few months.

The problem of reconstruction facing each manufacturer, or, in more homely phrase, the period of putting his house in order for private trade, is not an easy one. My opinion is that this will be best met by producing existing models for the immediate future so that there will be the least possible delay in delivery; and this is the policy the Enfield Co. will rigidly follow.

Even during the past few strenuous years we have not allowed our grip on the industry to be relaxed, and this will be recognised when we make public the result of our experiments and labour. The present time is not opportune; but I can at least say that what we shall have to offer the motor cycling world in the future will arouse the keenest interest, and that, I think, must suffice for the moment.

Opinions.—

From Mr. H. F. S. Morgan, the Designer of the Morgan Runabout.

I CANNOT pretend to deal with motor cycles, for I have always specialised in cycle cars. The cycle car is the necessary link between the cycle and the car. The light car does not fill the gap: it approaches too nearly to the car. The cycle car manufacturer must study the requirements of the motor cyclist even more closely than those of the car owner. It is true that some who in former days owned cars will find that a cycle car best suits the post-war condition of their pockets, but the majority of orders will come from those who have been (or were intending to become) motor cyclists, and who for some reason or another are not content with the motor cycle. I may add that the cycle car seems to make a strong appeal to the airman. Now the motor cyclist and the airman have been used to an essentially "sporting" type of machine. It is of no use to offer them a mount which will only amble along the road. There are any number of people who say (and write) that this is the sort of machine they want, but they are not the sort of people who buy.

Moreover, the motor cyclist takes some pride in the mechanical details of his "bus. He has been used to tinkering with it at home, and rather likes it—in moderation. But he has no use for a machine which demands incessant tinkering, nor certainly for one which needs expensive garage repairs.

Mr. H. F. S. Morgan.

The simple cycle car, which meets these requirements, will be in greater demand than ever after the war, now that so many have gained some mechanical knowledge. It will be impossible for the manufacturer to reach his limit of production for some time. He will not have the materials, and he will not have the men. An agent said to me the other day, "You will have no excuse now; you can get at once all the men that you require." This is not the fact, and we cannot wish that it should be so. If we could obtain at once all the men that we require, where would be the jobs for the men—some millions—who will return later from serving their country? We must "hasten slowly," and for some time the demand for cycle cars will exceed the supply. On the other hand, the demand will not be unlimited, and no machine has any chance of lasting success which has not special attractions of its own.

From Mr. Harold Bowden, Managing Director of the Raleigh Cycle Co., Ltd.

ONE of the most important things to consider from the British motor cycle manufacturers' point of view, I think, is the conserving of our home and colonial markets for the British motor cycle, which to-day is still superior to foreign productions.

The duty of at least 33½% should continue on all imported motor cycles and parts, otherwise the country will be swamped with the surplus outputs of foreign makes, and, through fierce competition we should be unable to continue payment of high wages to our workpeople, which, I think, we are all most anxious to do in order to avoid labour troubles.

The motor and motor cycle industries have rendered great service to the nation in the great war, and thereby deserve protection as some recognition of their services.

I hope an attempt will be made by British manufacturers to standardise their productions more and thus increase output. Most English firms produce far too many models, and give their customers too many options, which is fatal from a production point of view.

With the experience gained through the terrific "gruelling" experienced by despatch riders' machines during the four years of war, British motor cycle manufacturers should be in a position to produce post-war models as near perfection as possible, and all former weak points eliminated.

From Mr. P. F. Bennett, Chairman British Ignition Apparatus Association and Managing Director Thomson-Bennett Magneto, Ltd.

AS chairman of the British Ignition Apparatus Association, I feel bound to emphasise once more the facts as they are to-day in case there are any who have not realised the change that has taken place in the magneto industry during the period of the war.

First. The Government has been purchasing magnetos in enormous quantities for all classes of work. The result is that, at the present time, there is available an amply supply of magnetos for the British motor industry. The quantities produced by the British magneto firms are greatly in excess of the quantity that was imported from Germany before the war.

Secondly. The demand upon the efficiency of the magneto has been largely increased in severity to meet the needs of aero, tank, and other special work.

It is not too much to say that the safety of the Empire has been in the hands of the British magneto manufacturers, as without our Air Service and Tank Corps, Mechanical Transport, etc., we should never have won through. All these mechanical services have been dependent upon British magnetos. Realising this, there is no need for any anxiety as to the reliability of the British magneto for commercial purposes.

Thirdly. The demands of the Services have necessitated improvement in design, so that when the magneto factories are able to change over to magnetos designed in accordance with their war experience, the motoring public will have machines

Mr. Harold Bowden.

far in advance of anything they have previously known.

Lastly. We know exactly what the German has been doing, as the magnetos on crashed aeroplanes have been examined, and we know that had there been any startling new discovery the German Government would have had the benefit of it.

From J. W. Stocks, Pioneer Motorist and General Manager, Ariel Works, Ltd.

I WOULD like to thank the Editor for giving me this opportunity of wishing *The Motor Cycle* and its readers a Happy and Prosperous New Year.

The reconstruction period will necessitate some patience on the part of both buyers and suppliers—the former will be anxious to get machines as quickly as possible and the latter to assist them back to the memories of pre-war days.

One of the problems we have to face immediately is the question of prices. If the present high rate of wages is maintained, and the shorter hours do not result in increased output, everyone will have to pay higher prices all round, and I fail to see who will benefit. I think when it is appreciated that under existing conditions we cannot compete in the world's markets foreign competition will straighten out matters in due course.

What we require, without doubt, is a reciprocal tariff. Personally, I see no reason why my next door neighbour should be more offended because I charge him half a crown for coming into my house than I should be because he charged me the same amount to go into his.

From a business point of view most of us will have to look upon the last four years as a nightmare, particularly those firms who have had to devote practically the whole of their works to munitions of a kind quite different from their peace time productions, and start where they left off in 1914.

I am, however, sufficiently optimistic to think that when the petrol and other restrictions are removed there will be buyers to absorb the output of firms with up-to-date 1914 models for a year or two. Even those firms who are supposed to be ready with new models, in spite of the numerous extensions and facilities for increased output which have been made in nearly every works, will find the question of supplies of material a serious handicap. When the new Government gets into its stride, I think the restrictions which have taken over four years to introduce will be removed in practically as many months after peace is declared. Supplies will gradually overtake the demand, and by next November, when the cycle and motor exhibitions will again be welcomed, I think more normal conditions will prevail, though I do not for one moment anticipate that we shall be anywhere near normal prices.

Mr. J. W. Stocks.

Opinions.—

From Mr. Norman T. Downs, Managing Director of New Imperial Cycles, Ltd.

NOW that the war is ended the manufacturer is able to turn his thoughts to his normal productions, and, naturally, the prospect of improvements in motor cycles engages his attention.

So far as my company is concerned, we have designed, and, in fact, have been experimenting for some time with new models which embody improvements of considerable scope, but, owing to the suddenness of the close of the war, we have decided to defer the introduction of our newest models until the Olympia Show of 1919, and turn our attention to the production (with improved details) of our war models, as made for the Allied Armies.

Mr. N. T. Downs.

We shall specialise on two models only—a 2½ h.p. light tourist and the New Imperial 8 h.p. combination. By devoting ourselves to these two models we hope to obtain a larger output.

May we through your columns wish all motor cyclists a Happy New Year and a plentiful supply of petrol.

From Mr. Geo. Stevens, of A.J.S. Fame.

IF the motor cycling public will only be patient, now is the time for the motor cycle trade to put its house in order and determine that out of the anxieties and problems brought about by the war only good shall result.

As an expression of opinion I cannot say that the experience gained during the war has helped manufacturers in the matter of improved general design, but it will undoubtedly result in better and improved methods of production, which will ultimately result in not only reducing production costs, but will provide the rider with a more dependable and efficient machine. During the war manufacturers have certainly seen the advantage of:

1. Concentration on one model.
2. Quantity production.
3. Necessity for a more scientific knowledge of metals, their treatment, and their scientific distribution in design.

Other than the advantages which can be derived from the above, I suggest that the public will see very little change, either in general or detail design. That will come later when things become more normal.

Mr. Geo. Stevens.

From Mr. Geo. E. Rigby, of the Royal Ruby Cycle Co.

I AM certain there is a splendid era of prosperity before motor cycle manufacturers, and a tremendous output will be required to fulfil the demands both here and in our Colonies.

I am convinced the motor cycle buyers will demand up-to-date machines, with the very latest improvements, and, therefore, the manufacturers who put on the market their ordinary pre-war machines will not be satisfied with the results.

I am a very great believer in the future of the spring frame motor cycle, and when it is perfected I cannot see anyone buying the old rigid type, any more than anyone would think of now buying a motor cycle with a rigid fork or the motor car with a rigid chassis.

I have, therefore, spent a tremendous lot of time and money inventing, experimenting, and testing spring frame models, and, profiting by the experience gained during the war, I am placing a small number of models on the market in order to produce them in larger quantities.

From Mr. F. Hulbert, Works Manager, the Triumph Cycle Co., Ltd.

THE single-cylinder motor cycle has been my ideal machine since 1903, when I won the 200 miles reliability trial for the Edge Trophy on a Hulbert-Bramley fitted with a 2½ h.p. Minerva engine.

The most successful machine of the future, I consider, will be the one which will claim simplicity, efficiency, reliability, lightness, speed, power, and comfort, and I believe the single-cylinder can be built to these requirements.

Unfortunately, the good old days are past when Hart-Davies (who, alas! is no more), Lister-Cooper, and I used to make yearly tours to Birdlip and Sutton Bank to test our new machines, and the excitement in climbing these hills, when two and three-speed gears were unknown, was most enjoyable.

The advent of the three-speed gear has, of course, killed this sport, and even with a heavy sidecar attached a good single-cylinder machine will climb any hill on low gear, no matter how steep, so long as the back wheel will grip the surface.

This is why the A.C.U., in the Six Days Trials in 1914, went out of its way to find freak hills, which, to my mind, was most unfair to the manufacturers.

Owing to the length of these contributions and their unusual interest precluding condensation, we are continuing this feature in subsequent issues.

Mr. Geo. E. Rigby.

From Mr. W. J. Lloyd, of the Lloyd Motor Engineering Co., Ltd., Pioneer Designer and Maker of the L.M.C. Motor Cycle.

I THINK it is highly probable that my ideas on reconstruction will run very much in the same groove as the majority of manufacturers and designers in the industry. In any case, so far as my firm is concerned, we are standardising and simplifying construction with the idea of giving the public the best possible value for money.

As regards design in general, I am specialising on a spring frame Colonial model, particulars of which will be available shortly, when patent formalities are completed. Meanwhile, I use the term "spring frame" for convenience. Strictly speaking, it is more on the lines of a suspension frame, being an evolution of various ideas I have worked upon for the last twenty-five years.

The idea is to get away from a multiplicity of joints. Incidentally, I brought out a spring frame bicycle some twenty-five years ago, which was very successful, and in this suspension there were only two joints.

From Mr. W. H. Carson, of the Excelsior Motor Co., Ltd.

NOW that the time has come for us to return to our staple industry, the question of reconstruction is one of great importance, especially to those firms who have been engaged on other than motor cycle manufacture. Many of the employees accustomed to motor cycle building have been claimed by the Army, and doubtless it will be some time before they are permitted to return to their civilian occupation.

During the past four years the conditions under which motor cycles have been used have brought about many important developments, such as

stronger frames, larger diameter wheel spindles, more ground clearance, heavier gauge spokes, better mudguarding, etc.

Those of us who have been employed in other directions must not be satisfied to recommence where we left off in 1914, but must give riders the benefit of all developments which circumstances have made it clear must be adopted.

To market new models embodying these features will be a matter of time, especially as many firms will be engaged on completion of Government contracts.

Mr W. J. Lloyd

Mr. W. H. Carson

THE GARAGE PROBLEM

The Motor Cycle—where to keep it ???

THIS is a day of problems, and demobilisation and reconstruction provide the majority of them. Complex social and commercial matters have to be decided. Health and housing questions will have to be solved, and for the motoring public of the future, I venture to add, the problem of garaging.

The questions of housing and garaging are intimately connected, and there are several points of fact from which to commence their solution.

As demobilisation proceeds huge numbers of men will return to civil life, a fair proportion of whom, probably tens of thousands, have been intimately connected with motors on war service, many of them having had no previous knowledge of the internal combustion engine. These men will not be content to revert to shanks's pony or the push cycle either for business or pleasure. They are all potential purchasers of motor cycles, with or without sidecars.

Manufacturers, in appreciating the demands of this newly-developed market, will no doubt turn out motor cycles in numbers far exceeding any pre-war production. It is common knowledge that every maker is preparing for a larger output than heretofore.

The problem of storage now arises. The modern house is the most inconvenient place imaginable in which to keep a motor cycle. In most cases no outbuildings are provided, and even where they are, narrow front, back, or side entrances, or flights of steps, effectively preclude the entrance of a motor cycle. When the thousands of new houses, which election candidates have so glibly promised, materialise, it can safely be asserted that nine-tenths of them will be designed without a thought for the accommodation of even a bicycle, not to mention a motor cycle, and in any case the erection of such houses will take several years; in the meantime both new-comers to motoring and old-timers will be hard put to find the necessary cover for their machines.

The motoring world will soon have before it the prospect of large numbers of motor cyclists all clamouring for garage accommodation which does not exist. There are several ways of coping with this *contretemps*.

(1.) The agent who sells the machine, as an offshoot from his business, can run a series of garages for his purchasers.

(2.) The motor cyclists in any particular district can club together and rent some suitable building, or even build a properly equipped garage for their combined use on a conveniently situated plot of land.

(3.) There is a fine chance for speculative members of the building trade to erect communal garages on a big scale, but motor cyclists should strongly oppose any profiteering schemes which may be forced upon them.

(4.) Architects and builders of houses, whatever the value, should endeavour to provide, for either each house or group of houses, reasonable outbuildings properly designed to accommodate motor cycles—or cars, according to house values.

(5.) Garages could be erected and maintained by the local authorities, and the cost and expense charged by a special rate on the town's motoring inhabitants.

The first two suggestions are more applicable to the near future. The third and fourth ideas will undoubtedly be useful, in a lesser or greater degree, in due time, but for the moment the letting of suitable

existing buildings by the owners, or the renting and sub-letting by the motor agent or by a motor cycling community itself, are the principal ways in which garaging accommodation can be quickly provided. There must be many buildings in most towns which will become available with the cessation of war work. Many of the munition firms will have temporary shedding to

dispose of, which can be taken down and re-erected elsewhere.

The fifth idea, the municipal garage, savours of Utopia. Many local authorities are not yet so kindly disposed to the motoring fraternity as to consider such a proposition seriously, but, looked at from the point of view of public health, the idea is not so absurd as it may seem; motoring makes for good health, so does bathing; public baths are provided in all cities as a matter of course, then why not garages?

The majority of new motor cyclists will have to consider garage expenses as a necessary part of the running costs in the future. The rentals of any

How waste and uneven ground may be utilised for lock-up motor cycle sheds. There are many such pieces of ground available, even in thickly populated districts.

The Garage Problem.—

garages, such as here suggested, would vary considerably. The cheapest method will be that run by groups of motor cyclists without profit, except to provide a small surplus for building repairs and upkeep. A management committee, with secretary and treasurer, would seem to be necessary where this idea is carried out on a large scale. The agent who provides accommodation will quickly arrive at a limit; he cannot go on providing garage room for ever, but whatever he does in this way, the rentals asked should be kept as low as possible, or he will find it a serious deterrent to his sales. A reasonable figure which will just clear expenses is the best incentive he can give to a would-be purchaser who is faced with the accommodation difficulty.

Communal garages are much in vogue in the States, and not a few exist in this country, more particularly for car users, but unless the idea is developed quickly while yet the purchase of machines in a great many cases is under consideration, and before demobilisation frees many potential motor cyclists, there will be trouble in the wind for the motor cycle trade; no one will buy a machine if he has no place in which to keep it. He cannot leave it in the street, he cannot get it into his house, and all existing garages are full—what is he to do? The answer in many cases will be, "No garage, no motor cycle," unless a very special effort is made to provide the necessary accommodation.

I recommend this subject particularly to the notice of all motor agents, property owners, architects, and builders.

F.A.S.

A co-operative garage built on the plan outlined above is one way of solving the storage problem. All the sheds are heated and fitted with electric light. Ample room and convenience exist for washing down machines.

THE BLACKBURNE PROGRAMME.

Engines with Outside Flywheels in Four Sizes.

THE Blackburne engine with its outside flywheel for some time has been regarded as ideal by many motor cyclists, and it may come as welcome news that Messrs. Burney and Blackburne, Ltd., are introducing a complete range of their engines as units for manufacturers to fit, and also three models of motor cycle embodying them.

Two Singles—Two Twins.

These engines are $2\frac{3}{4}$ h.p. and 4 h.p. singles and 8 h.p. and 10 h.p. twins, all with outside flywheels and embodying the well known Blackburne features, such as detachable heads. The respective sizes of these engines are $2\frac{3}{4}$ h.p. (71×88 mm.), 348 c.c.; 4 h.p. (85×88 mm.), 499 c.c.; 8 h.p. (85×88 mm.), 998 c.c.; and 10 h.p. (85×97 mm.), 1,100 c.c.; and they

will be offered in both air-cooled and water-cooled types.

The three motor cycles will be a lightweight with two-speed countershaft gear, clutch and kick starter, chain-cum-belt transmission, and $26 \times 2\frac{1}{4}$ in. tyres, to sell at £60; a 4 h.p. model, with three speeds, $28 \times 2\frac{1}{2}$ in. tyres, all-chain drive, etc., £82; and 8 h.p. combination with 28×3 in. detachable wheels, all-chain drive, etc., £125. All machines will be fitted with Brampton Biflex forks.

The new lightweight Blackburne, especially, should make a very strong appeal, as very few engines of this size are now available. Several makers have introduced such engines, and among them may be mentioned the A.J.S., Sunbeam, Diamond, Hobart, Ilston, Precision, and New Hudson, but many are discontinued.

The 8 h.p. Blackburne, one of three machines to be manufactured in 1919.

RECONSTRUCTION— What Have We in View?

Reconstruction is the Keynote of Future Progress.

WE have to build up an Empire worthy of the men who have died for it and us. We are called upon to be the architects as well as the builders. We have to plan and prepare as well as to erect on sure foundations.

Out of the stress and agony of the years of war there has come to us a wider vision, a deeper consciousness of what is true and beautiful, the desire to erect a structure that shall live through the ages as typical of the greatness we have achieved and the greater things to which we aspire.

The First Steps.

We must start on our work untrammelled by the narrowing, selfish, and unenlightened conditions of the past. We must give very practical expression to our aims and ideals. We want to make our Empire a better place in which to live for all the sons and daughters of the Empire, not, incidentally, for a favoured few only. How are we to set about it? What are the practical things which must be dealt with in a practical fashion? Let us confine ourselves to material things, glad, indeed, if they may be furnished by contact with things spiritual, but being ourselves content to work in our own appointed field with the measure of vision granted to us, small though that be. So let us take the improvement in rates of wages and the better housing conditions which are immediately demanded by the manual workers—and not they alone—as the first step towards the abolition of poverty and the raising of the level of social life. For poverty is a crime in the well ordered State, whatever the proverb may say to the contrary. The housing problem cannot be settled by the individual: it is a matter for the State. The wages question, on the other hand, is a matter for the individual, chiefly for the individual manufacturer and agriculturist, for these are the real producers of wealth. The industries of the Empire are the springs from which flow the Arts and Sciences and all things good and beautiful. The “superior person” and the “idle rich” may no longer sneer at industry. Indeed, we have no room either for the superior person or the idle rich in the new state which we are building. But this is by the way. We are writing on the question of wages.

Unlimited Output the Solution.

These must be maintained at a far higher level than in pre-war days. Labour claims—and rightly claims—a far larger share of the profits of its labour than it formerly obtained, and, in any case, it insists—and again rightly—upon a minimum standard, which shall provide for the decencies and comforts of life, as well as for some of the so-called luxuries—we mean those things which should not be regarded as luxuries, but should be common to the lives of us all.

How is the manufacturer going to satisfy this demand? Well, it can only be met if the employers and workers each do their fair share of the task. Manufacturers must take full advantage of all the improved methods of production, scientific organisation, costing systems, the latest and best machinery, the employment of the best available brains, and “quantity production.”

There is no danger of over-production, at all events for years to come; but an intelligent, active sales organisation, covering the markets of the world, is the necessary complement to “quantity production.”

On the part of the workers there must be an end for ever to the stupid “ca canny” policy of the past. Each one must contribute to the output to the full extent of his power and be paid in full measure, according to the value of his contribution: in other words, payment by results.

Let us apply the argument to a particular case—that of the motor cycle industry. What is to prevent this industry developing, on the lines indicated, immediately? Here we think we write with actual knowledge of the facts of the case. There is probably no industry in the country better able to respond to the new spirit of the age than this, for it is on the eve of an extraordinary stage of development and progress, which, rightly understood and directed, means prosperity and all the good things that implies for all engaged therein.

An Estimate.

It may be rash to give figures which can be quoted against one at a later date, but we believe that there will be at least one and a half million motor cyclists within the confines of the British Empire as soon as machines can be made and supplied. Who is going to supply them, by the way, if not the British manufacturers? Obviously our American cousins in the main. We need not worry about our American cousins—one would rather say “brothers” now that we know their quality—at the moment, but we shall have to worry about them presently if the British manufacturers fail to realise the really wonderful opportunity now open to them, and fail also to realise that it can only be dealt with by “quantity production.”

They must think in thousands—in tens of thousands—and not in hundreds, as they have for the most part been accustomed to do. There is no difficulty in the way which cannot be overcome by intelligently directed energy and a wide and long vision. We know it means factory extensions, more plant, and more capital. All these can be provided for, and with much less delay, in our opinion, than is commonly believed.

Reconstruction—What Have We in View?—

No, the trouble is not in most cases that these difficulties are in the way, but rather that, with few exceptions, the possibilities of the future have not been clearly visioned. This is mainly because, among manufacturers, all thoughts have been concentrated upon war efforts.

But there can be no doubt of the issue in the mind of any person of intelligence who has found time to think of these things amidst the stress of war conditions, as some of us have contrived to do.

The future of the British motor cycle industry is one of assured success and prosperity if manufacturers will grasp their opportunities boldly and workers do their part loyally and thoroughly

To help to that particular end, we urge the formation of a National Industrial Council for the industry, with a workshop committee in every factory. Co-operative effort, a spirit of comradeship between master and man, a full recognition of the claims of labour, of administrative ability, and of capital. These things *must* be if we would build up the industry to the dimensions it should reach.

In so building up we shall do our share, in our own little corner, not only towards building up prosperity and happiness for all concerned in the industry itself, but also in the creation of a new and better country and Empire for the benefit of the generations to come, and so contribute our quota to the problem of reconstruction.

The lightweight motor cycle will play an ever increasing part in the life of the worker. "Back to the land" is a cry very persistent just now, especially in regard to soldiers and women workers. Housing accommodation being difficult to obtain in the country, the motor cycle will be largely employed to traverse the distance between home and the holding or the farm.

THE FUTURE AND THE LIGHTWEIGHT.

SOONER or later will come a time when every other man and every third woman will possess a lightweight motor bicycle. It will be used for shopping, for running to business and back, and for running to pleasure and back. It will certainly not be a hermaphroditic over-elaborated automobile de luxe on two wheels. It will be of a definite and distinctive breed which knows how to preserve its own identity and does not wish to ape its betters or pretend it is a colonial model, or a light sidecar machine, or half a motor car. It will be as the present bicycle for use and ubiquity, but it will be a saver and not a consumer of human energy. It will be the simplest combination of the simplest forms of engines, gears, and wheels. It will be "lightness combined with strength" *in excelsis*. It will be a hack not a Bucephalus. Thousands will buy it. Indeed, it will become so common that in time it will be the real and

true *omnibus*. The miner, the mechanic, the weaver, and the wood-worker will use it to get to and from work. Every large firm will need a special shed for storing machines, and the workpeople will club together to provide an attendant. None but the aged will be seen in the trams, and the suburban trains will cease to crawl. Large factories will arise turning out the workers' motor bicycle in thousands. Every ironmonger, tinsmith, paint and paraffin dealer will have exposed for sale in his windows two or three machines, and he will be able to supply parts and spares from stock. There will be no local repairing in the present accepted sense. Renewals will be cheaper than repairs.

Soon we shall see the beginning of that new epoch when every household will think it no more remarkable to possess a motor bicycle than it does to possess a mangle or a sewing machine.

C.R.E.

WHICH TYPE?

The Result of the Referendum Voting reveals the Great Popularity of the Flat Twin and the Single-cylinder Engines.

THE IDEAL SOLO MACHINE: THE DESIGN EMBODYING THE IDEAS OF THE MAJORITY.

The Ideal Specification.

ENGINE: $3\frac{1}{2}$ h.p., short stroke, 500 c.c., four-stroke, flat twin, air-cooled.
CARBURETTER: Two levers.
MAGNETO DRIVE: Gears, central position.
LUBRICATION: Hand pump, forced feed, and throttle controlled.
GEAR RATIOS: Four.
TRANSMISSION: All chain.
TYPE OF GEAR: Dog clutch engagement.
CLUTCH: Dry plate, multiple, cork inset.
FRAME: Sprung, diamond, duplex.
FORK: Druid type.
SEAT: Sprung saddle.
HANDLE-BARS: Semi-T.T.
BRAKES: Front in V rim; rear, expanding.
WHEELS: Detachable, $26 \times 2\frac{1}{2}$ in.
LIGHTING: Dynamo.

The Winner's Specification.

ENGINE: $3\frac{1}{2}$ h.p., medium stroke (square), 500 c.c., four-stroke, flat twin, air-cooled.
CARBURETTER: Two levers (semi-automatic).
MAGNETO DRIVE: Gears, central position.
LUBRICATION: Hand pump, forced feed, and throttle controlled.
GEAR RATIOS: Four.
TRANSMISSION: All chain.
TYPE OF GEAR: Dog clutch engagement.
CLUTCH: Dry plate, multiple, cork inset.
FRAME: Sprung, diamond, duplex.
FORK: A.B.C. type.
SEAT: Sprung saddle.
HANDLE-BARS: Semi-T.T.
BRAKES: Front, expanding; rear, expanding.
WHEELS: Detachable, $26 \times 2\frac{1}{2}$ in.
LIGHTING: Dynamo.

Notes on the Specifications for Solo Machines.

IT may not come as a surprise that the ideal specification for a solo machine which has been compiled by the voting of our readers is for an opposed twin of $3\frac{1}{2}$ h.p. Nevertheless, the $3\frac{1}{2}$ h.p. single was a very close second, so it may be said these two types offer the greatest possibilities to manufacturers.

In the voting, the flat twin leads all other types, although not sufficiently to permit one to assume that no other one is worth considering. The opposed twin finds favour with 40% of the entrants, while 36% specify the single. In round figures, other types were represented as follows: V twins 13%, four-cylinders 5%, less conventional types 6%. The object of the referendum, however, was not so much to find a

winner as to give the manufacturers some idea of the proportionate popularity of all points, and in this connection there is no doubt that the data now available will be of great assistance to the designer. This will be published in another article next week.

The ideal specification makes a composite machine which is illustrated above, and, while not departing from accepted practice, there are very few makers producing such a machine. The number of flat twin machines on the market at present are limited to less than half a dozen makes, therefore it is easy to compare their specification with that of the composite model. First, however, it should be noted that the type of spring frame shown in the drawing in no way

Which Type?—

indicates the suspension system readers had in mind. Our artist has drawn upon his imagination here.

In brief the specifications of existing $3\frac{1}{2}$ h.p. flat twins are given below:

A.B.C. (pre-war design).—All-chain drive, spring frame, four speeds. (This model in all probability will be abandoned.)

Brough.—All-chain drive, rigid frame, three speeds.

Bradbury.—All-chain drive, rigid frame, three speeds.

Douglas.—Chain-cum-belt, rigid frame, three speeds. The Peace model will have a spring frame.

Humber.—All-chain drive, rigid frame, three speeds.

The prize for the specification embodying the greatest number of points contained in the composite has been awarded to Mr. A. Woodman, of Blencathra, Maidstone Road, Chatham, whose specification is published.

THE IDEAL SIDECAR MACHINE: THE DESIGN EMBODYING THE IDEAS OF THE MAJORITY.

The Ideal Specification.

ENGINE: 8 h.p., long stroke, 1,000 c.c., four-stroke, V twin, air-cooled.

CARBURETTOR: Two levers.

MAGNETO DRIVE: Gears, behind engine.

LUBRICATION: Mechanical and hand pump.

GEAR RATIOS: Three.

TRANSMISSION: All chain.

TYPE OF GEAR: Dog clutch engagement.

CLUTCH: Single dry plate, cork inset.

FRAME: Sprung, diamond, straight tubes, girder.

FORK: Indian type.

SEAT: Sprung saddle.

HANDLE-BARS: Semi-T.T.

BRAKES: Front, contracting; rear, expanding.

WHEELS: Detachable, 28 x 3in.

LIGHTING: Dynamo.

The Winner's Specification.

ENGINE: 8 h.p., long stroke, 1,000 c.c., four-stroke, V twin, air-cooled.

CARBURETTOR: Two levers.

MAGNETO DRIVE: Chain, behind engine.

LUBRICATION: Hand pump, forced feed.

GEAR RATIOS: Three.

TRANSMISSION: All chain.

TYPE OF GEAR: Dog clutch engagement.

CLUTCH: Multiple, dry plate, cork inset.

FRAME: Sprung, diamond, straight, duplex.

FORK: Brampton Biflex.

SEAT: Sprung saddle.

HANDLE-BARS: Semi-T.T.

BRAKES: Front, expanding; rear, expanding.

WHEELS: Detachable, 700 x 80 mm.

LIGHTING: Dynamo.

Notes on the Specifications for Sidecar Machines.

IN the sidecar group, the V twin leads the opposed engines by a considerable margin, while the four-cylinder and singles are in the third and fourth positions respectively. It was more difficult to find the winning specification from the forms sent in by the big twin enthusiasts. The award, however, was eventually granted to Mr. G. F. Halliday, of Howcans, Boothtown, Halifax. The specification sent in by Lt. Vivian I. R. Clark, R.E., totalled almost as many points, but, although he voted for straight tubes, he qualified this item by mentioning his choice of frame as Indian, which, of course, has not straight tubes. The Indian type of forks, for which the majority

voted, was mentioned by him, but Mr. Halliday mentioned 1,000 c.c., whereas Lt. Clark's ideal was given as 930 c.c. The latter gentleman's choice in carburettor control, too, lost him a point.

The composite specification resembles those of the Indian and the post-war Clyno, but in all probability several machines of this type will be marketed ere long.

It is perhaps rather surprising that for sidecar work the three-speed gear gained a larger vote than four ratios, especially as the "four" led in the case of the solo machine. All-chain was easily first as an ideal transmission.

Comments on the Plebiscite.

IT is interesting to note that both winners are experienced riders owning up-to-date machines. Mr. Woodman informs us that his present mount is a 4.5 h.p. twin countershaft Zenith, astride which he tells us he has "enjoyed many a priceless hour," both solo and with sidecar.

Mr. Halliday's present machine is an 8 h.p. Sunbeam with dynamo lighting set, and his experience includes riding in South Africa.

Solo Engines.

Among the solo specifications there were a good proportion of those which were considered to be ideal for a dual purpose mount, yet the 500 c.c. engine came out on top with 32.7%, 550 c.c. being second with 21.5%, and 600 c.c. third with 9.8%, while the 650 c.c. engine scored 5%, equally with the 350 c.c. size.

The 300 c.c. engine scored only 3.8%, but below this size no reader gave a vote, while there were quite a number of large engines—up to 1,100 c.c., in fact—specified, both for dual purpose and purely solo work.

The Engines of the Sidecar Machines.

Despite the large number of readers who undoubtedly desire a machine which can be used as a dual purpose mount, *i.e.*, a single or twin between 500 and 600 c.c. capacity, the larger capacity engines received the biggest number of votes. That 1,000 c.c. was regarded as the ideal by no less than 31% may cause some surprise, since in pre-war days the tendency was toward a 750 c.c. engine. The latter only scored 19.8%, and was the next in order, followed by the 600 c.c. engine with 7.2%, and the "550" with 6.8%.

Larger engines than these, however, increased the big engine proportion by other sizes slightly more than 1,000 c.c., *i.e.*, 1,050, 1,100, 1,200, and even 1,500 c.c. were mentioned, while those between 800 and 950 represented a further 16%. The 500 c.c. engine was represented by 4.96%, which rather goes to show that a few users of the old-time 3½ h.p. are perfectly satisfied with such a machine for sidecar work. Considering the apparent advantages of the automatic

carburettor operated by a single lever, it is somewhat surprising to find that in both solo and sidecar class the voting was in favour of the two-lever.

Mr. Woodman (winner in the solo class) and his present mount, a 4.5 h.p. countershaft Zenith.

In the sidecar class over 60% voted for 28 x 3 in. tyres, while the 26 x 2½ in. size was regarded as ideal by 32% of the voters in the solo groups.

The Ideal Solo Single.

Taken separately, the specifications of single-cylinder solo machines made up a composite specification as follows: Long stroke 3½ h.p. four-stroke, air-cooled, gear driven magneto behind the engine, semi-automatic two-lever carburettor, all chain transmission, three-speed gear, dog clutch engagement, multi-dry-plate clutch, diamond spring frame, Druid type forks, front brake in V rim, rear brake contracting on hub. Tyres 26 x 2½ in., detachable wheels, semi-T.T. bars, dynamo lighting.

The reader whose specification came nearest to this composite is Mr. R. E. Kay, 43 T.A.S., R.A.F., Chattis Hill, near Stockbridge. It is interesting to note that the great majority of readers who forwarded "Which Type" forms were riders of long experience.

Mr. Halliday and his 8 h.p. Sunbeam.

The composite V twin was practically the same specification excepting that a 6 h.p. engine was substituted, while the ideal "four" included 1,000 c.c. long stroke air-cooled engine, combined with four-speed gear box, shaft driven magneto, sprung frame, 28 x 3 in. wheels.

Some Other Opinions.

One reader in voting for a flat twin added a rider to the effect that this type was his ideal only for the present, and that he favoured a water-cooled four-cylinder when weight could be reduced. Another suggested that the W.D. finish be retained, and several mentioned the desirability of lugs being built into the frame for sidecar fittings.

The conventional was departed from by several readers, and among the many items considered as ideal were quite a number of 90° twin engines, a few side-by-side twins and three-cylinder engines, magnetic, hydraulic, and friction transmissions and roller gears. Integral engines and gear boxes, too, were mentioned.

The result of the "suggestions" competition will be announced later, when we have had an opportunity of judging the huge quantity of letters received.

Quite a large number of forms came to hand after the closing date; in fact, every day forms still reach us from distant parts of the kingdom. In the meantime, the forms from Overseas have commenced to arrive in large numbers.

RIDER AND MAKER.

The Manufacturers from the Rider's Point of View.

MOTOR cycle manufacturers are more often "cursed" than blessed by the rider, despite the eulogistic remarks that are published occasionally in catalogues and advertisements.

In my early wheeling days youth and enthusiasm caused me to regard the manufacturer of a bicycle or a motor bicycle as a supernatural being, and one with whom I wished to be on particularly good terms. I imagined him sitting up at night with a wet towel round his head and a cup of strong coffee at his elbow, working out problems for the increase of my pleasure and recreation. Alas! my imagination was too keen. I have since discovered that he seldom does these things. A motor cycle maker is not always a rider of the machines he sells; there are exceptions to prove the rule, but the majority do not gain that valuable first-hand experience that alone can make the really successful producer.

"Ready for the Road."

Having thus aired a grievance, here are a few items for post-war policy which would ameliorate the lot of riders and improve our commercial relations Overseas.

I understand that most motor cycle manufacturers subscribe to an organisation which I imagine was formed to unite them for the common weal, viz., to benefit themselves. If this is so, then many of the reforms for which riders have combated will take longer in coming. Standardisation is one item, and when it comes I trust it will be made to apply not only for the makers' but the riders' benefit. It is safe to say that the production of motor cycles will increase during the next few years, and naturally if practically each maker has a different thread for nuts and bolts, it means that when standardisation becomes an accomplished fact huge stocks will have to be scrapped. If standardisation in threads were adopted immediately while the stocks are small and the tools about ready for renewal, the cost to the trade would be much less.

Another item in which makers are very much to blame is concerning the supply of tools and accessories. In some instances they are mean to a degree in connection with the outfit. Everyone knows what a pleasure it is to receive a well-equipped machine, with tools to fit every nut, also special tools for parts difficult of access. Unfortunately, the makers who adopt a liberal policy in this direction are few and far between.

A motor cycle maker advertises to sell a complete machine. How often, however, is it incomplete? A complete machine is one that is ready for the road; it should be supplied with lamps, warning instrument, speedometer, number plates, etc., and there should be nothing for the purchaser to add before he can take the machine on the road.

It only requires the accessory makers and the machine makers to get together to evolve a standard method of fitting for the accessories and for proper permanently fixed attachments to be fastened to the frame, handle-bars, etc., during the process of manu-

facture. This would dispense with flimsy clips which the accessory firms are compelled to supply because the motor cycle manufacturer does not embody these fittings in his design. What has made the great success of the Ford car apart from its price? In my opinion it is the fact that, when the car comes out of the works it is complete, and the owner knows that he will be able to use it at once in daylight or darkness without disbursing an extra penny for accessories.

In many instances the manufacturer's guarantee is not liberally interpreted; in fact, I would go further and say that the printing of it in many catalogues is a form of legal verbiage intended to exonerate the manufacturer from blame in the event of an accident, and to wipe out his liability to replace any part which should happen to go wrong—I will not say break or prove defective, breakages obviously would be replaced for the sake of his reputation.

I only draw attention to guarantees, as printed in catalogues, because I consider they are too one-sided. Also they do not cover a sufficiently long period. Three months to six months is far too short. Also there is no clause deciding whether the date of the guarantee extends from the day the machine leaves the works, or the day when the agent succeeds in selling it to a purchaser.

Then I come to a grievance which I have often heard expressed among riders of the touring class as distinct from those who take part in weekly competitions; it is that the ordinary purchaser is barely considered in comparison with the attention paid to a skilled competition rider. I hear that these riders are supplied with any number of spare parts, their machines are tuned up regularly at the works, and hosts of other minor attentions are shown to them. Doubtless their performances bring business to the manufacturer, and it is only human nature for the manufacturer to study their requirements; but he should not forget that the real support of his business is the ordinary purchaser who outnumbers the competition rider in the proportion of a hundred to one.

The Connecting Link.

I hope that no manufacturer who honestly desires to benefit the rider while making a legitimate profit for himself will consider my suggestions are written in a spirit of carping criticism, but with the hope that the British motor cycle industry will continue to hold the leading position in the world, and it is only by improving manufacturing and commercial methods that this supremacy will be maintained.

The link between riders and manufacturer is, undoubtedly, the pages of *The Motor Cycle*, and in justification of my views and criticism is a strong desire, as an enthusiastic rider, to witness the supremacy of British-made goods. The British motor cycle industry is at the top of the pinnacle, due to the perfection of its manufactured articles. This undoubtedly comes first, but next to it is liberality in business as apart from conservative narrow ideas.

SPECIAL FEATURE

OPINIONS. WHICH TYPE? RESULT OF REFERENDUM.
EMPIRE TRADE.

TIME TO LIGHT LAMPS

GREENWICH TIME.

Jan. 2nd	...	4.30 p.m.

" 6th	...	4.35 "
" 8th	...	4.38 "

Three-inch Tyres on Lightweights.

Messrs. Humphries and Dawes, Ltd., will fit 26x3in. tyres to their peace model lightweight.

An American Motor Cycle School.

During the war American motor cycle mechanics have been trained in a special school in the Harley-Davidson factory.

The A.C.U. Petrol Licences.

The secretary of the A.C.U. informs us that he greatly regrets the delay which has recently occurred in his office in dealing with queries relating to petrol licences. This has been unavoidable, owing to the fact that the Petrol Controller's Department has temporarily run out of the correct forms upon which application must be made.

Death of the Motor Trade Statistician.

We have to announce the death of Mr. Harry Hewitt Griffin, whose name will be familiar to many readers of *The Motor Cycle* in connection with the motor cycle show statistics which he compiled for this paper, and which at one time were a feature of our reports of exhibitions. Mr. Griffin was also responsible for the annual census of road traffic in various parts of the Metropolitan area. He was associated with the cycle trade in the early days, and a keen follower of cycle racing.

A Woman Soldier Motor Cyclist.

According to the Paris *Daily Mail*, a Madame de Gouraud Morris has been on active service as a motor cyclist. She took part in the Seine swimming race on Christmas Day as the only woman competitor.

An Old-time Motor Cyclist.

We hear that Mr. H. Belcher, one of the oldest motor cyclists in the country, has severed his connection with Messrs. A. R. Atkey and Co., Ltd., and bought the business of Messrs. R. Cripps and Co., Ltd., Lower Parliament Street, Nottingham.

The Price of Petrol in France.

There seems to be a good deal of profiteering in the sale of petrol in France. Prices are high, as 1.50fr. (about 1s. 2d.) a litre is being asked, and as there are approximately five litres to the gallon the price per gallon would come out at something like 5s. 10d.

Petrol is dear enough in all conscience in this country, but evidently it is not so dear as in the land of our Allies across the Channel. It seems rather hard to imagine why they should have to pay so much more than we have to.

The Industrial Reconstruction Council.

The first lecture of the second series arranged by the Industrial Reconstruction Council will be held in the Saddlers' Hall, Cheapside, E.C.2, on Wednesday, January 8th. The chair will be taken at 4.30 by the Marquess of Crewe, K.G., and a lecture entitled "Industrial Unity" will be delivered by the Right Hon. G. H. Roberts, M.P., Minister of Labour. Applications for tickets should be made to the Secretary, I.R.C., 2 and 4, Tudor Street, E.C.4.

Sale of War Machines and Parts in France.

The following prices were obtained for some of the rejected Army motor cycles sold by Government representatives in Paris recently: Griffon, £17; Moto-Rève, £6; Peugeot, £10; Rover, £44; Royal Enfield, £24; and Triumph, £20.

Sidecars fetched from 10s. to £4 each, so the condition of the lowest-priced sidecar can be left to the imagination.

Belts were sold in lots of 800 and 1,000, and a quantity of acetylene generators and large numbers of parts for cars, such as gear boxes, back axles, steering, brakes, etc., were sold at the same time.

Petrol Substitutes from South Africa.

South Africa has already given one petrol substitute to the world in the shape of Natalite, though, unfortunately, it is true that practically none has yet reached this country. Now a new product of a similar nature has been announced in the same part of the world, under the name of Penrol. This fuel appears to be very similar to that recently described in *The Motor Cycle* in an article entitled "Alcohol Carbide Fuel." It consists of pure alcohol saturated with pure acetylene, and having 0.3% of acrolein added, but as far as is at present evident this fuel is not based on the American experiments we described. It is claimed for the new fuel that it is both cheaper and more economical in use than petrol at its present price.

The recent meet of the Sheffield and Derby branches of the N.M.C.F.U. at Matlock. The weather was decidedly unfavourable, and the run demonstrated the inefficiency of the average mudguard. Over a hundred motor cycles were present, all but four being combinations.

Better Mudguarding.

Manufacturers are giving this matter attention, but to obtain the ideal result is "easier said than done."

A Trade Entrant.

Mr. Rex Mundy, the well-known competition rider, is opening a motor cycle depot at Brighton.

A Curious Address.

The Johannesburg depot of the Dunlop Rubber Co., Ltd., recently received a letter addressed, "Dunlop extra heavy fit this side first, Transvaal," that was posted in Mozambique. The address was evidently copied from the side of a Dunlop motor cycle cover.

Death of Mr. Harvey du Cros.

Mr. William Harvey du Cros, the founder of the pneumatic tyre industry, died on December 21st at his residence, Dalkey, Co. Dublin. In his younger days Mr. du Cros was a noted athlete in Irish amateur circles, and with the advent of the motor car he became an enthusiastic motorist. Mr. du Cros was seventy-two years of age, and belonged to a distinguished Huguenot family which settled in Dublin early in the eighteenth century. A year or two ago he retired from active work in the Dunlop companies.

An International Touring Trial.

An excellent idea has been suggested to us by Mr. T. W. Loughborough, secretary of the Auto Cycle Union, namely, that of holding a motor cycle international touring trial in 1920. A similar idea has already been put forward in our sister journal, *The Autocar*, in which it was suggested that the trial should start in Belgium, should touch some of the most interesting places which figured in the war, and descend *via* the Vosges into the French Alps, thence into Italy and back again to France, finishing up in Paris. The idea deserves the greatest encouragement, as any scheme that will further the wonderful alliance now existing between the nations which have fought and conquered is an excellent one, and well worthy of all the support which can be given to it.

The Motor Cyclist Spy.

Now the war is over stories are coming through of the wonderful exploits of our Intelligence Corps. It was the custom of our High Command, when they were anxious to obtain any special knowledge about the Hun military organisation (and there was not much that escaped their notice), to send a spy (usually a Frenchman who knew the country thoroughly and had a full inside knowledge of the Hun military machine) in an aeroplane behind the German lines, leave him to work there for a few days, and then actually fetch him back again by the same means.

The machine used was a specially-constructed B.E.12 type, and the pilot usually a well-known Birmingham racing motor cyclist who specialised in this particular work. It was undoubtedly a very risky commission, but he was brilliantly successful, and was rewarded by many military decorations.

These must have been some of the most wonderful exploits of the war. Very often the machine was hit by anti-aircraft fire, but it always managed to get back.

Popular among our Belgian Allies.

A prominent officer who has much to do with motor cycles in the Belgian Army writes: "*The Motor Cycle* reaches this depot regularly each week, and is read with the greatest interest by everybody. There is quite a scramble as to who shall read it first."

The Birmingham M.C.C.

At the inaugural meeting of the Birmingham M.C.C. held on December 20th many suggestions were put forward for the improvement of future competitions, social events, etc., and the club's 1919 programme promises to be a very attractive one. It was also suggested that the various motor cycle clubs should make a combined appeal through the A.C.U. to the authorities to have the Motor Restriction Order revoked. It was proposed that the local clubs might reopen motor cycling competitions by having an inter-club trial.

The Motor Cycle in France.

In an article entitled "*The Motor Cycle of To-morrow*," our contemporary *L'Auto* makes an urgent appeal to French manufacturers to wake up and turn out machines of the same type as those used by their English and American Allies.

The position is summarised in the following words, "If ten people in France buy uncomfortable motor bicycles without change speed gears, to start which they must be acrobats and run 100 yards, there will be 1,000 buyers who will interest themselves in the reliable complete motor cycle constructed for the practical purchaser."

The French writer's ideal is a machine of not less than $3\frac{1}{2}$ h.p., with rear springing, a good spring fork, wide mudguards, 3in. tyres—in fact, a practical English motor cycle. The flat twin is also spoken of favourably.

The article concludes by pointing out how the motor cycle can be brought up-to-date, and urging manufacturers to produce something really good. "If such a machine is built," writes our colleague, "the French will not regret it."

Outputs.

Enormous outputs are expected by several makers of motor cycles, and if rumour is not exaggerating we shall shortly see large numbers of new machines on the road.

A New Precision Engine.

The new Precision engine will be a 350 c.c. two-stroke single-cylinder engine which, we are told, will develop approximately the same h.p. as a pre-war 500 c.c. four-stroke. All revolving parts will have roller bearings, the lubrication will be automatic and continuous, and will not require a subsidiary tank for oil storage.

The Institution of Automobile Engineers.

The fourth meeting of the session of the Institution of Automobile Engineers will be held on Wednesday, January 8th, 1919, at the Royal Society of Arts, John Street, Adelphi, W.C.2, at eight o'clock, when Mr. L. H. Pomeroy will read a paper on "Influence of Valve Lift and Combustion Chamber Design on Consumption."

Cards of invitation to the meeting may be obtained on application to the Secretary of the Institution of Automobile Engineers, 28, Victoria Street, Westminster, S.W.1.

Kindly Appreciation.

Praise for one's work is always appreciated, and it was gratifying to receive from a well-known firm of engine specialists a warm eulogy of *The Motor Cycle's* work during the war years that are past.

They tell us that "Your constant placing before us of the hundred and one points of detail in motor matters with ever new views upon them; the comprehensive reviews of existing types, both of complete machines and parts; and the exhaustive descriptions of new developments, or possibilities of developments, have been of the utmost use to us."

This exactly sums up our aims and ambitions.

An Italian Army motor cyclist awaiting orders. A carbine, fixed on the off side by the forks, is usually carried on the outfit, which in this case is an Indian.

EMPIRE TRADE

**BRITISH MOTOR CYCLES
AND
THEIR SUITABILITY
FOR
OVERSEAS SERVICE.**

**POINTS OF POLICY
WHICH MUST
BE GIVEN ATTENTION
IN THE FUTURE.**

THE word "Reconstruction" has come to be connected with everything from the price of groceries to women's suffrage, and, in consequence, is rapidly losing its point. In this fact lies the danger that the importance of essential things may be levelled down to the value of those which are not so important, and, in the process, many things which require vigorous action may be allowed to go on along the line of least resistance.

We ask the industry to curb its impatience, to make careful preparations in changing over in order that the restart is made a sure foundation for business on better lines than before. This is not saying that we consider the average motor cycle manufacturer has been hopelessly antiquated in his methods, but there has been nothing done yet which it is not possible to improve, and "Do it better," in our opinion, should be a far preferable business motto than even "Do it now."

The present is the best opportunity the Trade is likely to have to put its house in order, and even three months' lost trade will be a price worth paying if the restart is made on "Do it better" foundations. If the change over is made hurriedly and temporary arrangements made for motor cycle output, the most may not be made of facilities, and such temporary arrangements may remain permanent.

Of National Interest.

Better facilities exist for development than most firms had before the war. In the interests of the motor cycle movement, and of the nation, it behoves every maker to make the most of them. The British industry in the future may then be an important factor in the commerce that must be created if this country is to maintain its position.

That Overseas trade must be more seriously considered has long been acknowledged by the thinking men in the trade; but, in many cases, not only new methods are needed, but new models also. Too long has the British manufacturer done business with a "Take it or leave it" attitude. Fortunately, to the maker, it

has not mattered a great deal, because his output has found a ready sale in the home country. There have been some, on the other hand, who have had energetic sales managers, keen to enlarge Overseas connections, but who have not had really suitable machines to develop foreign trade. The popularity of the American machines in the Colonies is proof positive that either our methods or our models—perhaps both—have been inadequate.

It seems strange that after the makers had been deaf to the demands of the Overseas markets on such points of ground clearance, it required a buying commission from Russia (which country probably knows less about motor cycles than any other) to induce the makers to adapt their machines to "foreign" requirements. However, quite a number of "Russian" models now exist, which are more suitable for the Overseas trade generally than most machines which were produced before the war. Never before have there been so many machines with 28in. x 3in. tyres, and that ample ground clearance demanded by many Overseas buyers. The magneto, too, has been considered and placed higher, and, in some cases, accommodated at the rear of the engine. The British maker has a chance now to meet his competitors in the Overseas market.

The 6-7 h.p. Overseas, made by a firm specialising in Overseas business.

The maker must not, as in the past, resign himself to be shut out of the most profitable Overseas markets merely because the difficulties, at first sight, are too great. The line of least resistance is not the direct line to success, and if it seems impossible to do business in a certain country because of competition, there are reasons which should be thoroughly sifted. But, first of all, it is necessary to compare the goods that are being offered with those with which they are to compete. The maker who cannot learn a little from his competitors must indeed be a very egotistical man. We know that confidence in one's goods is a very fine thing, but it is just as well to see where the "other fellow" is scoring, and the reasons therefor.

Nine British machines which are the nearest approach to "Colonial" requirements British manufacturers have yet offered are illustrated on the next page.

Some English Twins.

Excellent as these machines are, in most cases, they remain English models adapted for Overseas use. It is obvious that the new position for the magneto had not been considered when the machine was designed, while in a few cases the improvements consist merely of the embodiment of 28in. wheels. In fairness to the designers of these "Russian" machines, it is perhaps well to state that they were not claimed to be anything more than adaptations. The buying commissions visited this country with certain requirements clear in their minds, and to meet these requirements existing models were adapted, no time being given for special designs.

It would be unfair also to criticise British machines without mentioning the fact that the British designer has arrived at the big twin Colonial model from an entirely different direction from that along which the U.S.A. machine has developed, and in this connection, in our opinion, lies the secret of the successful

Representative British "singles" which are popular Overseas: The 4 h.p. Norton, 4 h.p. Triumph, and 4 1/2 h.p. B.S.A.

Empire Trade.—

8 h.p. Sunbeam

Overseas machine. * The British big twin has been developed as a sidecar mount, while in America and Overseas the majority of machines are used solo.

That is a point the British manufacturer should bear in mind. Let him ask himself if his big twin machine is suitable for solo work. The designers of several of the Russian models illustrated here can answer, without hesitation, in the affirmative, but some there are who will, in defence, assert that their product is not designed as a solo machine. Whether it is designed for sidecar or solo work, *nine-tenths of machines used Overseas are ridden solo.*

A Suggestion.

If any manufacturer, in considering ways and means of securing Overseas trade, will make enquiries—or, better still, send out a representative to study the requirements of riders abroad—he will find that the bulk of the British machines exported have been those most

8 h.p. New Imperial.

frames, and until British makers cover every one of these points they have opposition to overcome which decreases the chances of increasing output.

Since these demands are identical with those of the home buyer, there is no reason why the British big twin should not claim its full share of Colonial trade.

Another thing which must be borne in mind. America will not be the only competitor in the future. Italy is rapidly coming to the front with motor cycles which promise to fulfil many of the requirements of the Overseas trade. France, too, is a possible entrant as a serious competitor in the future, and unless the British manufacturer makes up his mind to study the world's, instead of local, requirements, the British motor cycle industry is doomed to take a second place in the markets Overseas.

The English motor cyclist may consider that too much attention is being directed to the Overseas machine, and

8 h.p. Matchless.

riders of their machines might readily obtain spare and replacement parts. This matter is closely allied to those other questions revolving around the financial aspect.

There appears no doubt that if the British motor cycle industry is to secure its fair share of Overseas trade, pre-war agency arrangements must be modified vastly. The Overseas buyer generally has been handicapped by being asked to pay cash for goods against documents in London, which means that an Overseas buyer, say in Tasmania, has to pay for his motor cycles before they leave England. This has compelled the majority of Colonial buyers to arrange with an exporting house in England to make financial arrangements for them. However, whether the English export house or the Colonial agent pays, the fact remains that the goods actually are paid for about two months before they arrive in the Colonies.

*The 5-6 h.p. A.J.S.

suitable for solo riding, and generally have been single-cylinder mounts with fairly good ground clearance, while great success has been earned by those having chain transmission. It must be remembered always that the Colonial rider frequently has to ford a stream, which is a difficult proposition for a belt-driven machine. American manufacturers have been singularly successful in the Overseas markets, because they have been able to offer a machine of a type developed under almost identical conditions as Colonial, and also different from anything procurable in this country. Thus it can be said that, while the American markets have had the lion's share of the twin demand, the British have monopolised the "single" market. This, of course, appears to be quite satisfactory, but the tendencies in the Overseas market point to higher power, larger diameter tyres, larger wheels, and spring

5-6 h.p. James.

that his requirements are being neglected. We think that when every point is considered it will be found that the Overseas buyer's ideal big twin is the home buyer's ideal also, and that the demand of the English solo riders for spring frames, larger tyres, chain transmission, etc., lines up with the requirements of the Overseas buyer. The results of the "Which type" referendum published in this issue reveal that the great majority of English sidecar riders require spring frames and 28×3in. wheels; in fact, there is nothing in the "home" specification which does not tend to bring the machine nearer to the Overseas ideals.

After the suitability of the machines themselves comes the important question of "service." Before the war, no arrangements were made by the majority of makers to ensure that the Overseas

8 h.p. Enfield.

Far better would it be for the larger manufacturers to open branch establishments in Australia, Africa, New Zealand, South America, etc. Some of the American makers have such branches in Canada, Australia, and Africa, and in addition have large depots in the principal cities. It seems absurd that, while some makers consider it a necessity to open depots in large towns in England, they overlook the greater importance of doing this in the Colonies, where their branches would serve a continent.

The Problem of Distribution.

Failing this, then, several makers with goods that do not actually clash should combine to open a distributing store in each of the Colonies and other countries where a demand, existing or potential, is to be found. Such distributing stores would solve the spare parts

5-6 h.p. Rover.

6 h.p. New Hudson.

8 h.p. Royal Ruby.

Nine British twins suitable for Overseas work:

Empire Trade.—

problem, and, instead of a rider having to send to England, and, incidentally, wait several months, the delay would be reduced to days. The knowledge of this would lend confidence to the Colonial buyer of a motor cycle, who in purchasing certain machines may have hesitated.

It is very frequently stated by writers on Overseas business that the American makers have the great advantage of "standardisation," which apparently is

8 h.p. Bianchi

confused with the system in vogue in the American automobile world of buying and assembling units produced in quantities by specialists. To associate this system with the American motor cycle industry is wrong, whereas Great Britain has the advantage. The American industry does not include engine and gear box specialists such as the J.A.P. and Precision engine concerns and the Sturmey-Archer Gear Co.

There are only two U.S. makers catering for the Overseas market, yet they

10 h.p. Pope

have a secure hold in our Colonies. This is a factor which has to be considered by British makers who aspire to the export trade. Consideration of these facts rather suggests that "too many models" is just as bad for an exporting nation as for an individual firm. Without taking this too literally, it certainly emphasises the necessity for closer co-operation between manufacturers. In this direction an "inter-standardised" Colonial model could be produced and made by a group of manufacturers, with a number of smaller engineering concerns

7-9 h.p. Harley-Davidson.

working for them, on the lines adopted by the Government in the production of aircraft. This would mean that a certain portion of the trade, instead of entering the Overseas market individually, would form a syndicate to produce and market one Colonial model. The parts would be made by them in their various factories or by smaller engineers under sub-contracts, and subjected to a system of inspection similar to the A.I.D. organisation. The central home of the syndicate would assemble the machines

7-9 h.p. Indian.

and organise the commercial side. Then it would be possible to open Colonial assembling centres also, with repair and replacements depots in all the Colonies. We think this idea is worth considering, especially by the smaller makers, who, instead of competing against their contemporaries in the matter of Overseas trade, could unite with them in concentrating that energy on the manufacture of some unit or part of a unit for the "inter-standardised" Colonial model.

Benz Aluminium Piston used in German Aeroplane Engine.

THE original Benz aircraft engines of 160 and 230 h.p. had light cast iron pistons, in which the piston head was lightly domed and reinforced by a perforated steel cone riveted to the head, and resting with its apex on the gudgeon pin. An Aviatik biplane with 230 h.p. Benz engine was brought down this year, in which were found aluminium pistons. These were the first to be found in enemy aircraft, and were also probably the largest diameter aluminium pistons used successfully prior to that date, i.e., early in 1918.

These pistons weighed 4.53 lb. each without rings, which weighed 0.095 lb. each. The total weight of the complete piston, with rings and gudgeon pin, was 4.91 lb., as compared with the standard iron piston, which weighed 6.72 lb.

Unlike the standard Benz cast iron piston, the domed head of the aluminium

piston was supported and strengthened by eight webs radiating from a central boss in the piston crown. The formation and shape of the webs are clearly shown in

Sectional views of the Benz piston.

the drawings. The piston rings are exceptionally deep in section, being 0.21in. deep and only 0.12in. wide vertically. The gudgeon pin bosses were fitted with steel bushes 0.080in. thick. These were "cast in" the bosses in the usual way. The gudgeon pins were 1.50in. diameter, and the bosses 2.55in. diameter. The method of fixing the gudgeon pin by a hexagon-headed set-screw and the split pin is standard Benz practice.

The chemical composition of the alloy, from a metallurgical analysis, proved to be as follows: Copper, 6.02%; zinc, 12.13%; iron, 1.42%; silicon, 0.31%; tin, nil; nickel, nil; manganese, trace; magnesium, trace.

The clearance allowance corresponded to 0.005in. per inch of bore at the head end and 0.0025in. per inch of bore at the skirt.

AN OPEN LETTER TO THE TRADE.

DURING the Reconstruction Scheme, is it possible for you to build a saucer track near London, say within a sixpenny fare; and another between Coventry and Birmingham; and a third at Stockport, Newcastle, or Manchester?

It would prove a wonderful testing ground for the Midland manufacturers, and, provided sufficient "pots" were put up, some wonderful speeds could be witnessed by the "man in the street."

Where can you find better sportsmen than the British, provided, of course, you play the game?

To make certain that each rider is a "trier" with at least some chance of success a standard time should be fixed for each lap, and unless the laps were accomplished within the "schedule," then that particular rider should not be allowed to compete in any other race on the same day.

I maintain that Brooklands is too large, and, in addition, it is too far from Town to get a large "gate." So who will be the first to put up the "needful" to lay the foundation for a Saucer Reconstruction track, or shall we have to wait until the Harley-Davidson get their "Reconstruction" programme going?

Things are going to hum in motor cycle circles. So here is jolly good luck to the coming boom. W. COOPER, Lt.

The Motor Cycle and the Health of Democracy.

The Political and Social Aspects of Motor Cycling, and the Great Possibilities of the Cheap Utility Mount.

"Ixion" attacks an Old Problem in a New Way, and suggests a Means to Solve It.

IN this article I momentarily abandon—with apologies to tolerant readers—my usual semi-technical, semi-jesting vein, and don the cap of a hopelessly impractical visionary, inviting our readers to forget for a moment the sporting and engineering aspects of our common hobby, and to consider its political and social aspects. Lest I should continue in this solemn tone with strings of sonorous polysyllables, I will now ask my friend Bill Brown to address the meeting.

Bill Brown (loquiter).

"How d'ye do, gentlemen? You don't know me, so I'll explain that I look after the gas engine, dynamo, and general power and light fittings in a small pattern-making establishment in X—Street. Hours, 6 a.m. to 6 p.m. daily, with sixty minutes for dinner. Knock off Saturdays at 1 p.m. Wages, 45s. pre-war; post-war? I'll wait and see. Age, 48. Married, six kids; and I'm proud to say five of them are boys.

"Mr. 'Ixion' says the first thing I'm to do is to explain where I live and why. I live in X—Street, close to my job. You mayn't know X—Street. It was built about the year one. Looks like it. Feels like it. Doors and windowframes all warped. No bathroom. No coalhole. Front door opens straight on to the street. Back door opens straight into—well, they call it a "yard"; it's a gloomy sort of gangway between two back-to-back rows of dirty old cottages. The gangway is choked with small wash-houses and coalsheds, and—well, we keep the back door and windows shut, even at midsummer. The staircases are so steep and rotten we don't let the little 'uns go up and down them alone. Landlord won't do anything. Why won't the landlord do anything? Because he can let this hovel ten times over for seven and a tanner a week if I turn rusty and quit. High rent for such a hole? Of course it is. You see it's like this. I could get a better house three miles out on the Meadowsweet Road for 6s. a week, with a garden in front and vegetable plot behind. So could any of my neighbours. But what price coming in three miles for a 6 a.m. start six days a week? Workmen's trams, of course. I know all about them. Then the dinner hour. If I cycled out I'd get wet through twice a week, and my digestion isn't any too good; I'd sure pay for it, because I wouldn't get out there much before 12.20, and I'd have to start back with my stomach full at 12.45.

"Mr. 'Ixion' says I'm to tell you what a good time I have, and what I do with my money. Well, it just goes. I spend a bit on liquor, because it bucks a

fellow up. I put a bit on a horse most dinner hours, when there's any racing; otherwise on football. So would the Pope, if he'd as dull a week as mine. Evenings I spend in the pub. The missus is busy washing the children or the crocks or the clothes, and the kitchen isn't exactly a palm court at such times. Saturday afternoons I go to a football match, where I shout myself hoarse and catch cold. Saturday evenings, the pub. Sundays, a good lie-abed, then a pipe and the *News of the World*: later, more pub. What else is there to do? Saved much money? Didn't used to: but during the war what with bonus and no racing much, and those Government swipes we did put by quite a bit. It'll soon go now, I expect."

* * * * *

("Ixion" resumes).

Well, gentlemen, that's my friend Bill Brown's story. I don't pretend it's typical of his class: but it's fairly typical of X—Street, which is a longish street: of all the streets like X—Street, and there's a bigish block of them: and of large similar rookeries abounding in similar old-fashioned industrial towns. By the way, Bill didn't tell you that he looks more like 60 than the 48 to which he owns: that much the same might be said of Mrs. Brown: and that the Brown youngsters are rather a pallid, pasty crew, though as sharp as needles.

I think the Brown *ménage* is a blot on our civilisation. It is a C3 household, physically, mentally, morally, and spiritually, and perhaps K4 if you try to grade it in terms of real happiness. Moreover, a motor cycle is a plank in my platform for ensuring that the little Browns found A1 homes when they are big enough to put the banns up.

It is fairly clear that if the life of men like Bill is to be worth living, he wants:

(a) Shorter hours. (b) Better housing.

He will get shorter hours when he and his mates cease to restrict output.

He can get better housing on one of two conditions:

(1.) If the factory is moved. (2.) If Bill's home is moved.

Consider these alternatives. If the factory is bodily shunted out along the Meadowsweet Road, Bill will have a modern and wholesome residence somewhere near it: but, unless he chances to develop a fancy for gardening, he won't have a hobby to occupy his spare time. He will quite probably booze and gamble as he did in X—Street from sheer ennui. The other alternative is to move Bill, and let him live away from

The Motor Cycle and the Health of Democracy.—

his work (as clerks, directors, and other moneyed people invariably live away from their work). The dinner hour is the key to this problem. For health and comfort a two-hour dinner interval would be the solution: Bill could then walk or cycle to Meadowsweet Road for dinner without ruining his digestion. But Bill won't hear of a two-hour dinner interval in an eight or ten-hour day; because he values daylight evenings. (If harder work during working hours ever comes into fashion, he may get a five-hour day, when a two-hour dinner interval would not matter.) So Bill should be made more mobile. He is too old to walk or cycle. Like all other sane people, he detests trams, tubes, and suburban trains. A motor bicycle would solve the locomotion problem.

Can Bill afford a motor cycle? There are a lot of "ifs" in the answer. In 1914 thousands of artisans owned machines, priced at upwards of £35 apiece, especially in the more prosperous districts of York-

shire and Lancashire. In 1920? We do not know how much post-war wages will stand. We do not know how much post-war machines will cost. We do know, on the other hand, that there are scientific production shops in which even the charwoman gets £1 a day, which suggests that with full-steam labour and first-class brains wages can be high. We also know that it is possible to sell a 20 h.p. car f.o.r. at the factory for £77; because this has been done. If Bill had not wasted his substance on beer and betting (for which we cannot blame him), he could certainly have bought a 20 h.p. car of this kind long ago. If some producer had marketed a simple motor bicycle at the corresponding figure of, say, £20, Bill could have bought one before he got married, and added a sidecar later.

If some manufacturing genius succeeds in producing a "motor cycle for the million" at £20 or so, he will do much towards substituting an A1 population for those C3 millions the war has revealed.

Reconstruction of the Motor Cycle Industry.

Advice from a Member of the Committee of Reconstruction.

THE successful reconstruction of the motor cycle industry is not wholly dependent either upon the Government or upon the industry itself. Neither one has power to attain the desired end without the full collaboration of the other. Within the industry itself the main needs are a fuller appreciation of the advantages of co-operation in any or all of its forms and a better realisation of the economies resulting from quantity output and reduction of the number of types manufactured. If my information is at all correct, motor cycle manufacturers need not starve for lack of capital with which to develop their businesses, provided that their products, even though they have been produced on a small scale, have at least shown themselves to be of meritorious quality. The motor cycle industry has not yet quite shaken off that attitude of suspicion which characterised many British industries before the war. In this respect it might well take an example from the commercial motor vehicle manufacturers. These latter, owing to the circumstances of their war work, have been brought into very close contact with one another. This contact has engendered mutual confidence, and the whole industry now pulls together in a way that would have been impossible a few years ago. Motor cycle manufacturers have not had quite the same incentive to collaborating, but I cannot help thinking that they have failed to take the best advantage of such opportunities as have occurred. Mere common membership of a central society or association is not sufficient in itself, unless the activities of that central body are generally supported and its meetings thoroughly well attended. We all know what a nuisance committee meetings can be and how common it is to feel that, when they are over, little or nothing has been achieved. They have, however, a merit which is not always apparent, inasmuch as they bring people closer together and encourage free interchange of ideas.

The motor cycle industry must look largely to the Oversea markets, the possibilities of which are immeasurable. To succeed in these markets postulates

production on a big scale and at a strictly moderate cost. It is only when quantity output exists that the big expenditure necessary to support an efficient selling organisation throughout the whole world becomes possible.

At the same time, as I have said, all the efforts of the industry cannot suffice in themselves unless they are wholeheartedly backed up by the efforts of the Government. The industry has been thrown into a state of temporary confusion. It has lost a great deal of valuable goodwill. This was not allowed to slide away through any fault of the manufacturers, but was actually torn from them by the Government as a consequence of the necessities of war. It is, then, not a case of an unprogressive industry asking to be helped on to its feet, and claiming that the Government shall make good its deficiencies. It is rather a case of an industry from which the Government has taken something of immense value, which in common fairness must be returned before the account can be regarded as honestly closed. Putting the thing in plain English, my personal opinion is that the motor cycle industry cannot be properly reconstructed unless it be given the safeguards which would result from the imposition of a tariff applied to all machines imported from foreign countries into the British Empire for a period of not less than five years. With such a tariff on a fairly substantial scale, the industry, if properly organised, should be capable of regaining its goodwill. At the end of the period, the tariff could be reduced or removed altogether, and the industry ought then to be able to hold its own. The proposal is not, therefore, an advocacy of tariff reform in its ordinary sense. It is merely an advocacy of emergency legislation to meet a purely artificial state of affairs, which really amounts to a serious handicap imposed on British manufacturers in their endeavour to fight foreign competition. Once this handicap has been removed and the proper balance re-established, it is up to the industry to justify itself and hold its own against all and sundry.

CANTAB.

The BINKS 3 Phase, Jet Damping AUTOMATIC CARBURETTERS

The CARBURETTER YOU MUST EVENTUALLY BUY

IT GIVES results quite impossible with any other, and is used by the Champion and the Amateur alike. It is quite automatic—from dead slow to the utmost speed is got by the simple movement of one lever. It gives a perfectly marvellous tick over, a dead slow pull on top, an instant easy start, and utmost power; all the worries and annoyances of other carburetters are absent on the Binks. No tap twiddling or ruinous petrol consumption; makes the machine silent and imparts a flexibility never dreamt of before.

Price 49/-

+ 50% advance

COMPLETE WITH SIX SPARE
JETS, KEY, AND INSTRUCTIONS

MR. R. D. O'DONOVAN,
THE MASTER OF SPEED.

His marvellous record-breaking feats at Brooklands on his Norton startled the whole trade. He uses and advises a Binks, and says he has proved the Binks the fastest carburetter made.

Endless other events of all descriptions have been won on my carburetters, but the testimony of the two gentlemen shown above renders further examples unnecessary, they are both good men for you to copy.

10,000 unsolicited testimonials received from the nobility and gentry the world over.

Ladies and Gentlemen—The superiority of my carburetters is so obvious that it is with confidence that I advise you to get one on a month's trial, and I believe that you will get an amount of pleasure out of your machine you never anticipated before.

C. BINKS, Ltd., Phoenix Works, ECCLES

Address me personally on important matters.

In answering this advertisement it is desirable to mention "The Motor Cycle."

THE MANUFACTURERS' TROPHY,
won by Mr. Robbins, London to Edinburgh and back. Mr. Robbins' total errors at the controls were less than 39 secs. *Motor Cycling* says: "A truly marvellous performance."

**SENT ON ONE MONTH'S
APPROVAL TRIAL ON THE

AND TREATISE ON CAR-
BURATION, FREE.**

MR. A. C. ROBBINS,
THE MASTER OF RELIABILITY,

Winner of the much coveted Manufacturers' Trophy, the blue ribbon of events. He used a Binks because he proved after trials that it was the best carburetter that was obtainable.

VITESSE

The "G.N." owes its Reputation for Performance and Service to the following features:

SIMPLICITY—The keynote of the "G.N." is its lightness, obtained not by cutting down the weight and strength of essential parts, but by effective simplicity of design and the use of high-grade materials.

ACCESSIBILITY—Both engine and chassis have been so designed that every detail is completely accessible and all adjustments can be effected with the least possible trouble and without dismantling.

EASE OF OPERATION AND CONTROL—The "G N." Cycle Car is easier to handle and more responsive than either car or sidecar combination; owing to its low centre of gravity, correctly disposed weight and effective system of springing, it is steadier on corners and holds the road well at all speeds.

RELIABILITY—Apart from lightness, the great point obtained by simplicity in design and absence of intricate parts is reliability, and

experience both before and during the War has proved the "G.N." to be dependable under severe conditions of service and over great mileages

LIVELINESS AND SPEED—The "G.N." possesses liveliness to an unusual extent, due to its light weight and high-efficiency engine. It possesses a reserve of power under all conditions, and especially scores on hills.

RUNNING COST AND MAINTENANCE—*Petrol Consumption* is very low; the average 55 m.p.g., but mileages considerably higher are frequently obtained. The "G.N." is extremely *light on tyres*—a set of standard tyres will do, on an average, well over 8,000 miles, a point of interest when compared with the tyre wear of a motor cycle. Necessary *replacement of parts* are few, and when required, quite inexpensive. More important still, owing to the extreme accessibility, the time and cost involved in fitting

FUTURE

DEMANDS.

The
New Model Combination
v. The Light Car.

By H. Tapley-Soper,

Author of
"Dartmoor as a Touring Ground."

THE recent turn of events on the battlefield permits us to think again of our old sport without that shadow which has overclouded such thoughts during the past four years. From time to time we have been wont, when in the company of fellow Knights of the Road, to refer to the happy days to come, but such expressions have gradually been losing the true ring of conviction. Now, however, all is changed, and we can, with the gentleman in Punch, exclaim, "What abaht it?" to which the cryptic reply, "What abaht what?" will be quite sufficient.

What the Public Wants.

The only thing that now matters is the new mount, so what about it? What does the manufacturer propose to do for us? The concentrated experience of the past four years should enable him to produce something incomparably superior to the makeshifts of pre-war days. He starts practically with a clean slate and a fair field, the world's markets before him, and a *clientèle* with an appetite which requires no whetting. But we, the purchasers, shall differ in one important respect—we shall be much more exacting, more critical, perhaps in some cases hypercritical. The fact is we now know something about machines. Our experience of various makes enables us to recall the salient points of each design, and we are able to appreciate the pre-eminent feature of this or that make—the gear box of one, the transmission of another, the accessibility of a third, and so on. And what is the corollary? It is as simple and natural as a milliner's display to a woman—we want all the good things.

But we want them all in a single machine. The firm which can produce such a machine is going to approach the ideal and grasp the market. Individual fads which do not increase efficiency, such as round tanks, and sidecars with *retroussé* noses, will not count. Reliability, accessibility, efficiency, and standardisation are the points which will score. The Ford car has proved it. The motor bicycle must follow.

Immediately prior to the war the cult of the sidecar combination was rapidly increasing. Initial cost and subsequent upkeep had a lot to do with it, and will be a more important factor in the immediate future. Enthusiasm for the light car was certainly on the wane, at any rate amongst those of moderate incomes. A valiant attempt had been made by designers and manufacturers to produce a light car which in the matter of price was intended to compete with the sidecar outfit. The consequence was the appearance of a number of inefficient contrivances which did their producers no credit and gave their purchasers endless trouble and anxiety. The small car costing from £200 to £300 is another proposition, and does not concern the man who only has from £70 to £120 to spend.

The Pros and Cons.

At the first blush, especially to the inexperienced, a small car is generally a more pleasing proposition than a motor bicycle combination. "It affords greater protection from the elements," "It is more comfortable," "is more 'classy,'" etc., are the favourite arguments of the tyro. For a man who must face all weathers, and whose appearance is a matter of

(Left) The author and his £100 sidecar outfit, and a £100 cycle car (on right). Some interesting and original points in favour of the sidecar are put forward by Mr. Tapley-Soper.

Future Demands.—

prime import, the first point can at once be conceded. As regards comfort, many men, with only just a dash of the sportsman in their composition, prefer the exhilaration of the saddle to the "too old at forty" feeling associated with lounging in a car—either large or small, the latter often so narrow that it affords less comfort than the saddle of a well-sprung bicycle. As for the passenger, all the ladies, including several well over sixty, whom I have driven declare their preference for the well-appointed and comfortable modern sidecar. The man of experience in these matters knows that a *reliable* light car in pre-war days cost anything from £50 to £100 more than a combination, and unless he bought a certain American make, well known for the funny stories which cling to it like barnacles to a ship's bottom, he purchased an unknown quantity: a contrivance which was neither fish, fowl, nor good red-herring—generally an attempt to produce a brougham at the price of a perambulator. Whereas the motor bicycle and sidecar market offered for a much smaller sum the choice of several vehicles, backed by the experience of output, the knowledge gained by exacting trials, and the testimony of thousands of riders. Further, such combinations are faster, cost less to run, carry a better guarantee, and, instead of being in the experimental stage or in the lowest grade of their category, both as regards quality and efficiency, are easily pre-eminent in their class and of known reliability and practically fixed design. In fact, a motor cycle combination scores every time over a cheap four-wheeler except on the one point already mentioned.

The chances of getting wet and dirty on a modern combination are nothing compared with what they were a few years ago. Improved mudguarding design and the evolution of suitable and easily donned overalls have practically eliminated these discomforts, and seeing that nine-tenths of the riding done is for health or pleasure—not because one has to do it—mud baths and rain douches can generally be avoided by putting the ride off until to-morrow night or next Sunday, which is a *practice as common to the light car owner as to the motor cyclist*. Personally I would as soon ride through a rainy day, well protected by proper overalls and rubber boots, on the saddle of a motor cycle as under a fusty hood behind a steamed screen through which it is often difficult to see the road. I remember one friend at least with

whom I have done many a mile through Dartmoor mist and fogs who could never be prevailed upon to use the hood of his car except as a concession to the fair sex. In fact, there is a good deal to be said in favour of the country on a wet day. The fragrant perfume of wet vegetation, the subdued chirp of the small birds, and the impressive stillness, followed by the coming to life of the countryside when the rain ceases, provides a welcome change to continual sun and clear skies.

Army Life.

So much for the relative values of the cheap light car and the first-class motor cycle combination. Now let us consider the riders of the next few years and their requirements. What demands is the effect of Army life likely to create? Certainly there will be a much greater appreciation of fresh air and outdoor life. There will be less fear of getting in a mess

—the horrors of greasy hands or a taste of petrol will not be so real. The use of tools will be approached with less reluctance; the ability to shift for one's self will have become almost second nature, and the power to "do things" and escape from the conventions of pre-war days will be greater than ever. Military life will have added many to the army of men who take a pride in their knowledge of motor cycles and who are able to appreciate the countryside.

What of the Lady Rider?

The influx to our ranks of the emancipated lady rider, from the W.A.A.C.'s and the W.R.E.N.'s, will, I venture to think, be considerable. Not only will she take more freely to the solo machine in the company of the male friend, but they will also want to drive the husband's mount. And why should not a couple of girls jointly own and manage a fully-equipped outfit? Then there is the large number of maimed men, particularly those deprived of a leg, to whom the motor cycle will be a godsend. And what of the munitionier who has saved a hundred or so? All these classes will augment the ranks of the "open air" brigade. It is therefore the manufacturers' duty to recruit them by producing

a machine which will combine the utmost comfort for both rider and passenger—a machine that will not engender the "anxious" feeling of possible breakdowns owing to silly little troubles which the uninitiated are unable to locate. Such a machine must be of the "foolproof" variety—efficient and robust, and without frills. The initial outlay must be

The tip-up Clyno sidecar. This, from the writer's point of view, is a desirable feature.

Transmission on the "off side" is a boon on sidecar combinations, and all adjustable parts should be accessible from that side.

Future Demands.—

reasonable, and the upkeep as low as possible. To meet these requirements it should be turned out in large numbers and its parts should be standardised.

The Family Sidecar.

The design of the solo motor cycle I will leave to the young "bloods"—perhaps there is not much room for improvement. But I should like to say a few words about the heavy combination—the machine that will be demanded by the family man, who was in many cases the solo rider of pre-war days. You know the sort of outfit I mean—a machine that will easily carry in comfort such loads as we were accustomed to see pull up at seaside or moorland resorts. 'Pa on the saddle, the sporty nipper on the carrier, and 'ma and the youngest squeezed into an inadequate sidecar with the lunch and the spares. The mere fact that such loads *could* be dragged about suggests that it ought to be possible to design a combination that would accomplish such feats with some degree of comfort.

I remember on one occasion seeing a double-seated sidecar attached to, I think, a Chater-Lea which to some extent fulfilled these requirements. I followed it for some miles across Dartmoor, and, although it was heavily laden with three passengers and much luggage, it appeared to be well up to the job. This is the class of machine that I think should be developed to meet the requirements of the man of moderate means. It should have at least an 8 h.p. engine, flat or V (I will not presume to say electric lighting and starter); a strongly-built roomy sidecar with an ample grid for luggage, and a carefully-designed carrier, that neither rattles nor rubs a hole through the tin for the spare supply of petrol. The carrier should be provided with a detachable chair-like fixture, equipped with apron, etc., as a protection against dust and rain, for an extra juvenile passenger.

Some Important Necessities.

The wheels should all be interchangeable, and a spare should be provided. The practice of cocking the latter up at the back, or between the car and the bicycle like the flywheel of a steam-roller, should be abolished. A locker might be designed for it under the sidecar, or a "well" provided at the back of the body under that portion over which the hood folds back when not in use. Of course both sidecar and bicycle should be well sprung, and should be designed as a *single unit*. The man who buys a high-powered combination seldom goes to the trouble of detaching his machine just for the pleasure of indulging in a solitary "blind." The sidecar should also embody that excellent "tip-up" feature of the Clyno combination. Such a design permits of easy access to the rear side of the machine without standing on one's head or flattening one's avoirdupois across the sidecar.

Reminiscence of this uncomfortable position reminds me of another suggestion, viz., that the driving chains should most certainly be on the "off," or right, side of the machine, as the rear chain is in the Sunbeam, and if possible the carburetter and magneto should also be on the off side, and in such a position that the brushes can be easily got at.

Another Sunbeam feature that is well worth adopting is an oil bath for the chains, which should

be enclosed in cast aluminium cases, which are more easily adjusted than those language-provoking contraptions made of sheet iron or old biscuit tins.

Such a combination as I have suggested would necessarily be fairly heavy—much too heavy for a woman to lift on to the stand for wheel-changing, etc. It must therefore be provided with some form of mechanical jacking apparatus for bicycle and sidecar. Now a few minor details.

Standardisation of Details.

What about carburetters? Every observant rider knows how carburation is affected by atmospheric conditions. Cannot someone design a carburetter which can be adjusted by means of a milled nut, or a thumbscrew, from the *outside*? Bowden wire, although very excellent in its way, also has a distinct weakness. That beastly little blob of solder to wit. If it tears away on the road, as I have known it to do, one is absolutely helpless unless a soldering outfit is carried and the owner possesses much knowledge and patience. Adjustments for the stretching propensities of these wires are also unsatisfactory, and if the wires rub—as they are almost bound to do on a bicycle—one's anxiety increases as strand after strand rubs through. This sometimes occurs at corners which are out of sight and are not easily noticeable. An adjustable nipple must be designed to replace the solder blob, and some form of sheath must be provided to guard against destructive friction.

Now we come to bolts and nuts. If you give a child a box of crayons, the first attempt at a picture which will be produced is sure to need the employment of each colour. Likewise the nuts on a motor bicycle. Did you ever come across such an assortment as is to be found on a motor cycle and sidecar? A friend with whom I discussed this iniquity suggested the simile of the child and the crayons, and the office boy, or apprentice, with a free hand in the nut stores.

Surely this provides a splendid opportunity for standardisation. It will, I know, necessitate a working understanding between those who make and assemble machines and the makers of accessories, but it is sure to come sooner or later, and why not now? The result would be a greatly diminished toolbag.

Easily interchangeable controls to meet the requirements of the maimed should be possible, and in this connection a feature of an early car which I once possessed might be worth incorporating. This was the inter-operation of both clutch and brake—an arrangement that has much to be said in its favour in cases of emergency. A serviceable front wheel brake, perhaps of the Lea-Francis type, will also be demanded. The front wheel brake of the past has proved little more than a subterfuge for complying with the law—the practical value was *nil*.

A combination on these lines would, of course, require a substantial car-designed countershaft gear box with at least three speeds. The mudguards should be wide and of the latest approved pattern. The saddle should be of ample proportions and easily adjustable. Optional dull or plated fittings is a desideratum.

If any firm contemplates the issue of a machine along these lines I shall be glad to become an early entrant for its delivery sheet, and can promise a list of friends who will follow suit.

An Open Letter to the Trade.

By B. H. DAVIES.

Prospects of the Future and Suggested Lines of Development.

GENTLEMEN,—Our mutual absorption in more urgent and less pleasant tasks has prevented my addressing you in this fashion for some years past. To-day my first business must be to congratulate you on the versatility with which you threw your energies into novel channels when half the world went mad four and a half years ago, and on the extraordinary efficiency with which you blossomed forth upon an astounded universe as so many super-Krüppts. I know you astonished us, and I rather suspect you astonished yourselves. We are proud of you.

In the second place, I assure you of your old customers' patience and sympathy in the very formidable task of switching over from munition work to motor cycle manufacture. These are trying days for that section of you which men call Labour, and I daresay that even Capital does not feel wholly comfortable. Excess profits can make a hole in all but the most opulent balance sheet. Ancient prestiges and goodwill require consolidating after a moratorium of so many years. Mushroom firms are casting covetous eyes on your old entrenchments. The cost of material and the wages of labour touch fabulous heights. Men say prices must sink, but one can conceive that they may not. In the meantime, the middle classes who formerly consumed your wares are not too prosperous. I can understand that some of you do not feel too sure of your markets. Nevertheless, there will always be a bright future for good motor cycles. In the old days British motor cycles were the best in the world bar none. In the new days they will be better than ever, because we have out-designed and out-manufactured most of our cleverest rivals in munition work, and if the greater task was within your powers, you will not fail in the lesser. Believe me, you need not worry.

Rejuvenation.

You makers are probably most concerned at the moment with the relations of Capital and Labour. Queer doctrines are certainly abroad, and frank co-operation is impossible so long as greed and suspicion are prevalent on both sides. During the last four and a half years all classes have been fighting shoulder to shoulder against a common foe, and have brought out of the battle a deeper sympathy for each other's points of view. Many a member of what an old friend of mine persists in describing as the "parasite" class can now picture what life in a slum tenement on 25s. per week can imply, or what an ever hovering spectre of unemployment means, or what ten or twelve hours per day in bad air and a frightful racket are like. Many a quondam Bolshevik has a new comprehension of the fact that brains and initiative and technical skill are not universal attributes, and require their peculiar stimuli. We all believe that when the soldiers flood

the factories we shall build up a new spirit of sympathy and mutual comprehension, and that greed and suspicion may dwindle and disappear.

And now we come to speak of our more technical expectations. It is good to know that the industry is to be rejuvenated by a certain amount of new blood. I remember some years ago meeting a shrewd friend outside the Press View at Olympia. "What's the Show like?" I enquired. "Forty copies of the X—, and a dozen opium dreams by half-baked engineering students," was his terse summary. Quite a libel upon you, I grant, but with a grain of fact in it, like so many libels. Well, what do we hope for from our caterers, old and new?

Reduce both Weight and Cost.

Comfort, in the first place. Quite frankly, we have no further use for boneshakers. Many of us will carry the relics of shell shock or gas gangrene or a shattered bone to the grave with us. But that's hardly the point. Even in 1914 one or two firms had proved that a motor cycle, being a one-tracker, can be made *more* comfortable than any car. In the future, uncomfortable machines have no chance outside the very cheapest class.

Cleanliness is another item on *our* waiting list. We quite admit that no brilliancy of design can keep a fast machine clean on dirty roads. But we think quite an ordinary brain could make a machine keep cleaner than some of them did in 1914, and we are perfectly certain that the job of removing dust, mud, grease, and burnt oil need not take a tenth as long as it used to take. You all know that up to 1914 you could tell a novice because his machine was kept clean: the old hands had far too much sense to attempt the impossible. At the same time we hated going about in a filthy condition. It is up to you to remove this reproach.

Light weight is a cherished ideal with many of us. We read of aeroplanes which carry more than the equivalent of their own weight at 100 m.p.h., and of aero engines which weigh less than 2 lb. per horsepower. We find it difficult to believe that a motor cycle must either weigh considerably more than its rider, or else be jiggety and unreliable. Please give us a comfortable, staunch, all-purpose machine at 150 lb. as soon as ever you can. The girls, the elderly men, and the disabled soldiers want it badly.

It is daring to mention price in days like these. Let us hope that the wiseacres who prophesy a sixty per cent. drop in costs during the next three years are right, and that all you have learnt about costing and production during the war will be valuable in peace. For there is an urgent demand for a Ford motor bicycle. The working man wants it. The middle-aged working man has not got a single outdoor hobby

An Open Letter to the Trade.—

of a sporting kind. The majority of the middle classes will want it, for they have been impoverished. The ex-Second Lieutenant will want it. In the R.A.F. alone there are 30,000 youngsters, who have grown accustomed to life on £400 a year, and thousands of them will not earn more than £200 for many a long year when they are demobilised. If Ford can make a 20 h.p. car to sell at less than £80 f.o.r. Detroit, what can you make a simple bicycle for?

I know that some of you burnt your fingers over cycle cars in the premature booms of the past. You look at the scars occasionally, and say the sidecar is good enough. In any case, those classes who will never again have as much "spence" as they used to have, are looking for something between a light car and a motor cycle.

What of the Overseas Trade?

Various correspondents urge me to press a variety of suggestions upon you. Our old friend the unpuncturable tyre crops up again: and certainly a puncture on a motor bicycle is far worse than it is on a car. The enclosed and integral speedometer drive—you should be able to contrive this? Listing a completely equipped machine, if only as an option? Cannot you guess how annoying it is to spend the first delirious week of ownership in buying umpteen accessories to make a machine ready for the road, and then to learn from subsequent experience that half the stuff you have bought is intrinsically dud or hopelessly unsuited to your own particular machine? Nickel plating, embossed letters on crank cases, oil drips which do not drip—those, of course, are mere memories of a hideous past.

A little wail comes to me from Overseas. "We showed we were patriots in the war. We died for you by the thousand in Gallipoli and elsewhere. From start to finish most of the Colonial troops were 'storm' divisions. After the war, will the trade give us the same attention that a customer in Brixton can rely

on? We do not want to buy American goods, but if British firms do not curse us and support Overseas agencies, what are we to do?" I think that letter can only have one answer, gentlemen.

Kick-starters and Mechanical Oiling.

We are watching eagerly to see whether you have solved the problem of electric lighting for solo mounts. It is the brightest and cleanest light we know, and we appreciated it highly on the best 1914 passenger outfits. Of course, it is dear, and we cannot all afford it. But we hope you can supply it, and if you include lugs and a drive on all machines, those of us who can't buy it immediately will save up and have it later.

Lubrication? No, we are not lazy. But there are two jobs in relation to motor cycling which we all hate, because they demand labour without intelligence. One is mending the tyres, and the other is graduating an invisible oil supply. We have no use for peering at an invisible drip to see when the next pumpful of oil is due. Car engines attend to their own lubrication, our engines should do the same.

The Prime Essentials.

Please don't jump to the conclusion that we are returning to our old hobby in a carping spirit. If you read this letter twice—which, of course, you won't—it will dawn on you that it is a stupendous piece of camouflaged panegyric. How so? Well, what are the two prime essentials of a tophole 'bus?

1. Reliability.
2. Speed.

I haven't said a word about either of them because you've long ago given us full measure of both,

pressed down and running over. All we ask now is best described in khaki slang: we plead for a little more "spit and polish," a few better gadgets—non-essentials all of them, but serving to perfect the finest pastime in the world.

Yours in gratitude, respect, and hope,

B. H. DAVIES.

The 1919 Cleveland two-stroke lightweight—one of the few two-strokes produced in America. This is a "new" view of the machine, and reveals many details which hitherto have been obscure.

THE FREE USE OF PETROL.

IT is announced by the Board of Trade that the Motor Spirit Restriction Order, the operation of which has been suspended until January 10th, will be revoked entirely from that date. Licences to obtain motor fuel still remain in force, but the Petrol Control Department are prepared to issue new licences and to increase the quantity allocated to existing licence holders.

The action of the Board of Trade, though tardy, is none the less welcome. It is generally felt that the Motor Spirit Restriction Order might have been suspended as soon as hostilities ceased, while it was always thought that the thirty-mile radius concession was somewhat absurd, as it would have been impossible to have enforced it. It is understood that all reasonable requirements will now be met.

Rolls-Royce and Ford Models.

Extremes of the Future Market.

ALL sorts of changes have been predicted with regard to the motor cycle of the future, but, viewing the outlook both from the points of view of riders and manufacturers, there is no particular reason to think that the old order, as regards the variety of machines produced, will be in any way restricted. The best known of our manufacturers will proceed to follow their own sweet wills as hitherto, though stimulated, perhaps, by keener competition, but one change is certain—that we shall arrive at greater extremes than in the past. We shall have the Rolls-Royce among motor cycles and the Ford—the first-named being a machine produced for the “select few,” and the latter, rendered not only possible but certain by the many changes that have taken place in the manufacturing world, the necessity for increasing output and finding adequate employment for our huge factories, etc., produced for the multitude.

The Rolls-Royce.

Recently I have conversed with manufacturers who are enthusiastic upon concentrating on this model—the luxury solo mount. One of them outlined his plans to me. His idea is to produce a really hot stuff flat twin, which is to possess every possible refinement in the way of modern equipment, etc.—mechanical lubrication, electric lighting, and a standard of finish which will place it in a class to itself. No expense is to be spared in order to obtain the zenith of comfort, tractability, speed, and durability, and the price of the finished article will most assuredly debar it from anything but a very select market. This price, however, is to include a first-rate system of service and a very generous guarantee—though the latter will automatically become void should the owner attach a sidecar! You buy the machine, if in difficulties you wire for a mechanic—indeed, the Rolls-Royce system is to be followed throughout within reasonable limits—but if you attach a sidecar you become an outlaw, beyond the pale of sympathy and support!

When I expressed the opinion that, attractive though the scheme appeared, the price was apt to kill the whole thing, I was assured that, provided the machine was positively paramount and exclusive as regards quality, there would be no doubt as to a market. Take it to Oxford or Cambridge and ask £120 for it, and there would be men ready to buy so long as they were getting the very best that could be produced. With the initial purchase the expense would cease, and, durability being one of the main points, one would be assured of a good second-hand price. There is no doubt a good deal in this argument, as there are unquestionably many motor cyclists who are not particular to thirty pounds either way so long as they get what is notoriously the best, and if we have the Ford motor cycle this somewhat snobbish spirit will be strengthened among the silver spoon gentry.

I know another manufacturer who intends concentrating on a four-cylinder luxury model which will be presented at a somewhat exclusive price, but the bulk of our makers rightly contemplate producing mounts of “medium” quality at medium prices.

The Quantity-produced Machine.

A certainty within the next five years, it is difficult to prophesy as to what form the Ford of motor cycles will take. One is inclined to think there will be some competition in this line, and that more than one type will make its *début*. But whatever c.c. may be chosen, the Ford motor cycle, like the Ford car, must have something more than cheapness to recommend it. It must be handy, reliable, and foolproof, these features being infinitely more necessary here than in the more costly type, because scores of fools will buy it. Like the Ford car, it must be capable of enduring neglect and hard usage—suitable for commercial requirements and all-weather riding.

There is an immense demand for an ultra-cheap lightweight, capable of going anywhere at its own

“Chinook’s” ideas of a quantity-produced model of the Ford type and a super de luxe model on Rolls-Royce lines. The cheap proposition (on left) is a single-cylinder, two-stroke, shaft drive, two-speed, flywheel magneto, and the simplest frame construction. There are no limits to the scope for elaborate finish on the aristocratic type, but it is difficult to get beyond the best accepted constructional details.

Rolls-Royce and Ford Models.—

speed, and, above all things, cheap to run. Hundreds of working men are waiting for it, though not prepared to take the plunge till it has actually established itself. An equal demand exists for the ultra-cheap delivery machine—suitable for commercial delivery and for the requirements of working men who desire to take their families afield.

One might suggest the two-stroke as the goods for the lightweight—a two-stroke of ultra-simplicity, having an all-chain drive and an inexpensive selective clutch gear on the lines of the Enfield. Produced in quantity it could be turned out at an absurdly low figure. The engine should be self-oiling on the lines of the Velocette, and the petrol consumption must be low. It should be capable of 150 m.p.g. at normal speeds, and should leave the factory fully equipped with all accessories for the road—brazen lugs being provided for all accessories—horn, lamps, etc. Petrol and oil piping should be cut down to a minimum, and one would suggest the integral unit system, the gear being contained in the crank casing, pinion driven, so that only one chain will be employed. If this can be cut out and a final shaft used, so much the better, the whole transmission then being oiled from the engine, so that the rider will have nothing to do but fill up with oil and petrol and look after his cycle parts.

The Commercial Machine.

This should not be less than 700 c.c. Apart from its commercial value, many would buy such a machine in preference to the lightweight if it were suitable for solo riding. It should be suitable, but whereas a three-speed gear would be essential for commercial requirements, this might be cut out advantageously for solo riding—a good countershaft clutch, Indian fashion, taking the place of the gear. This would render the machine lighter and cheaper, and it would be by no means difficult to produce a design which would permit the use of the gear box or clutch at will, the two machines being identical except that one would be a three-speed model and the other merely a clutch model. Personally, I have great faith in the clutch model solo mount, and it is to be borne in mind

that the machine for the multitude will be of the low compression, low volumetric efficiency type, capable of pulling hard at low speeds.

Where the Money goes.

Where the money goes at the present time is in minor fittings. It is not difficult to turn out engines under the quantity system, and the same applies to frames, sprockets, chains, etc. The price of carburettors, saddles, etc., is absurdly high, and something simpler and less costly must be arrived at. Similarly, the minor accessories run away with the money. Tot up what it costs to rig a machine with lamps, horn, tools, spares, etc. Magnetos are bound to be costly, but there is every hope of British quantity production in this line. It is cheaper for the manufacturer to buy accessories than it is for the private owner, and there are many advantages to be derived from this system. The manufacturer can choose accessories, all of which are in keeping with the machine, of proper size and weight, for many riders appear to possess no judgment whatever in these matters. Similarly, if the manufacturer chooses the accessories he can make proper provision for their permanent anchorage, so that the rider will no longer be troubled by a horn which insists on slopping round the bars and a lamp that vibrates its lens loose.

These are but a few points which strike one when viewing the problems of the future. It is to be hoped that we shall see a general tendency in the direction of rigidity and simplicity with quantity production. Is it not time the old pedal cycle ideas of mudguarding were finally abandoned in favour of shields—not only on account of their inefficiency, but because cycle mudguards rattle loose and afford a thousand points for the settlement of mud and rust? Much thought and good brains will be necessary if the Ford motor cycle is to appear in that stage of permanency which will warrant its lasting success, for manufacture of this kind does not permit of annual changes and "improvements"—those little annual additions "for next year's catalogue" for which we have all paid through the nose. It must be five years ahead of its time—if not someone will be badly stung. CHINOOK.

The popularity of permanent camps in the country with those who work in cities has of late years been increasing with leaps and bounds. In the future, when the motor cycle becomes the machine of the masses, these summer homes will be found in large numbers several miles from the towns, and the health of the workers will in consequence be greatly improved.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Herford Street, Coventry, and must be accompanied by the writer's name and address.

TAXATION.

Sir,—I am glad the question of unequal taxation of motors is being taken up by you, and I hope your efforts will be pursued until success is obtained.

The simplest and most satisfactory way to overcome the trouble would be, in the opinion of hundreds of motorists with whom I have discussed this subject, to put the whole of the tax on the fuel. In this way, the heavier the machine and the oftener it was used the greater would be the tax.

Taking a 12-16 h.p. car, for example, an extra tax of about 4d. per gallon would still admit of such a car running upwards of 3,000 miles without exceeding the present £4 4s. tax. Whereas a man who only used his car on Saturday afternoons or Mondays could keep his tax within £1.

SWIFT.

WHY NOT A PEDAL ACCELERATOR?

Sir,—I should like to make a suggestion through the medium of your most interesting and instructive columns, viz., Why not fit a pedal type accelerator in addition to the ordinary hand-controlled throttle? I am sure this would be invaluable in traffic, as the hand throttle could be set to give a steady "tick over" when the machine is stationary, combined with instant acceleration when required, and continual "tap twiddling" to avoid stopping done away with.

This would, of course, apply chiefly to sidecar outfits and to drivers who do not object to using their feet in lieu of their hands for the control of the machine, and the pedal could be arranged on the same side as the foot brake, therefore automatically decelerating when the machine is required to be stopped.

W. R. FRANCIES.

STANDARD SPEEDOMETER DRIVE.

Sir,—Now that the motor industry is being reconstructed, it would seem the right time seriously to consider the question of driving the speedometer mileage recorder or revolution indicator by means of a special shaft. This would be a permanent attachment, and not subject to the ailments from which all speedometer drives suffer more or less. The flexible cable could be attached direct to this standard shaft, and all that could possibly give way is the flexible cable itself. The life of this cable is, of course, in proportion to its speed; or, I should say, in inverse proportion to its speed—the slower it travels the longer it lasts. I would propose that the flexible cable should not under any circumstances run at a higher rate than 550 revolutions per mile. On Government aeroplanes, use is made of a gear box to reduce the speed of the flexible cable to one-quarter that of the screw or propeller speed, the latter running at 1,800 revolutions per minute; thus the flexible cable runs at 450 r.p.m. The speed of the flexible cable should be borne in mind by the designer; and the method of attachment of the flexible shaft, as well as its outer covering, deserves to be made a standard throughout the trade, so that private owners can choose what speedometer they like, and move it from one car to another or change it for another make of speedometer without any trouble.

I will at this stage make no suggestion about the method of attachment, but would propose that the motor industry consider the questions above referred to, with the idea of agreeing to a standard fitting; and, if agreeable to the trade, I shall be glad to design a method of attachment. If there is already such an attachment on the market, I do not think that speedometer makers will be likely to object to utilising it; but it should be a simple one, and a strong, permanent fitting.

B. BONNIKEN.

THINKING IMPERIALLY.

Sir,—We sympathise with your contributor "M.T., Subaltern," who gave his opinions on the suitability of British motor cycles for Colonial use in your issue of December 12th.

We have no hesitation in agreeing with him. The average British motor cycle is built to suit British conditions, which are by no means the same as Colonial conditions. The makers of the Blackburne motor cycle fully recognise the necessity of giving Overseas riders what they want, and to meet their requirements have designed a real Colonial model—not a British model altered in a few details, but a motor cycle designed first, last, and all the way through as a Colonial would desire it.

The machine is not an idea, but an accomplished fact, and it has been under test for some considerable time. We question if any motor cycle built for British conditions could follow our Colonial model over what we term our Colonial testing track. We question if any Colonial would ever find it necessary in the course of his usual trips to cross such country as that over which our Colonial model has been tested out, and if "M.T., Subaltern," cares to give us a call we shall be delighted to take him over the course.

We have thought imperially, and can promise Colonial riders something of much more use to them than our sympathy.

BURNEY AND BLACKBURNE, LTD.

Tongham, Surrey.

FLAT TWINS.

Sir,—Your contributor "Ixion" has always, in my opinion, been a little humorous and inclined to the sarcastic in his many comments which have appeared in your columns, and having read his notes in your issue of December 19th respecting flat twins, I must say he is trying to be more humorous and sarcastic than ever.

I should like to say a few words in the hope of broadening his views, as I consider his statements have a tendency to "mar" rather than make any advancement and enthusiasm in new designs, but he should not class them all alike. I am afraid "Ixion" is writing of something very much out of date; something, I think, which will not be seen in the new inventions which have to come—that being the poor lubrication of flat twin engines. When he warns readers not to buy new flat twins because of the design being poor, and infers that the front piston will be seized up, whilst the rear tappets emit greenish fountains of oil, he only advertises the fact that he is entirely out of touch with some of the scientifically constructed engines that will shortly appear.

May I whisper in "Ixion's" ear that I know of a certain flat twin designed on scientific principles embodying many unique features, which have never been seen before, one of which is lubrication by pressure to all bearings, and after a three hours' test at 2,500 r.p.m. there were only seven drams of oil in the crank case, each bearing, as well as the cylinders, etc., receiving its full share on correct mechanical principles.

Has "Ixion," I wonder, during the past two or three years been inside an aero engine factory, and noticed the magnificent workmanship and wonderful designs, which have gained for the British nation the supremacy of the air. Is he aware that many of these features will be embodied in some of the flat twins for post-war service.

It is an old tradition "the weakest must go to the wall." In the near future I feel sure "Ixion" will be greatly surprised.

HENDERSON SIDECARS.

LEONARD B. HENDERSON, A.M.I.A.E., Managing Director

THE A.B.C. MOTOR BICYCLE.

Sir,—I have read the comments concerning the A.B.C. light car and motor cycle, and would like to reassure your correspondents on the points they raise.

Concerning "E.W.B.'s" comment, I would certainly not think of allowing the engine to revolve in an anti-clockwise direction, and I regret the slip in the wording which led him to believe that in the diagram the drive is shown in forward gear. Actually the reverse gear is illustrated.

With regard to Mr. H. G. M. Hobbs's letter, I can assure him that there will be nothing in the way of "spoiling the ship for a ha'porth of tar," as he states, in any of our products, and the equipment already in view has detachable and interchangeable wheels, as well as a dynamo lighting set, but this will necessarily be an extra.

Mr. R. M. Wiggs's comments concerning straight tube frames are very much to the point and true in principle. I certainly did denounce the fetish of the straight tube frame, because it has been more of a fetish and a talking point than a point of sound technical design and reason; and one or two people may have misunderstood my meaning, as the article did not give my reasoning quite fully.

Any number of machines have made a talking point of their straight tubes, despite the fact that the frame was a four-sided figure. Straight tubes have no bending stress when, and only when, they form a perfect triangle, and a four-sided figure with straight tubes brazed into the lugs is far worse than a four-sided figure, for instance, with bent tubes, and consequently no sharp corners at the lugs.

A motor cycle is subjected to many other stresses than purely vertical ones; therefore, even a perfectly triangular frame (if it can be obtained) does not fill the bill unless it is triangulated laterally as well. In other words, to have no bending stress at all, one must have a kind of three-cornered pyramid design. Therefore, the designer can either assume that he has got a triangular frame and consequently no bending stresses, or he can assume and realise the actual truth, which is, that there are stresses in numerous directions, such as torsional ones, etc., and design his machine accordingly.

My experience has taught me over and over again that a flexible structure is a far more reliable one than a rigid structure with a sharp corner somewhere, as, of course, all the stresses are localised in this corner.

Mr. Wiggs says the straight tube frame is only a "fetish" when the members are unscientifically arranged, and this was really the whole point of my denouncing the "fetish" of the straight tube frame. I should very much like to see Mr. Wiggs substantiate his point when he states "it has been demonstrated on several occasions in the pages of *The Motor Cycle* that proper triangulation is perfectly feasible and convenient both for motor cycle and cycle car frames," by his letting me have some particulars of these demonstrations (in view of my remarks above concerning rigidity in every direction), and I would remind him that the very machine to which he refers is well known for the flexibility of the frame when cornering.

With regard to the short paragraph by "Ixion" under the heading of "A Bet," he had not the facts of the case quite as they were, neither did he complete the story.

The general arrangement drawing of the machine had been made, and the engine certainly was one that was adapted to drive dynamos previously, but it had to be modified in design in a dozen different ways in order to make it suitable for motor cycle work. The bet was to get out the detail drawings of the whole machine, and have one on the road in three weeks, and it certainly was to the extent of £100 a day. Nothing was standard on the machine; even the hubs, spindles, and cones were special, as they both combined cone brakes. The gear box required patterns and castings to be made, for which drawings were not even prepared.

There is only one frame lug similar to our previous design, and the rest were practically carved out of the solid. The tank, of course, was new, and enamelling and plating had to be done. The three-speed gear was of an entirely new pattern, running in the flywheel on roller bearings throughout, and the brakes operated on quick pitch threads.

Including drawings, patterns, castings, machining, fitting, erecting, enamelling, and plating, the whole job was done in exactly eleven days, and the machine was on the road ten days to the good (and it is still on the road).

I received Mr. T. O. M. Sopwith's cheque by the first post on the 12th day. GRANVILLE E. BRADSHAW.

A MYSTERY.

Sir,—Can anyone give me a solution of the following, which occurred whilst I was on leave recently. I have ridden a motor cycle since 1912, but confess to being completely baffled. A friend and I on a sidecar combination had had a splendid run, and on arriving at the top of a slight hill the engine started racing. As the roads were in a very wet state, owing to a heavy downpour of rain, I immediately came to the conclusion that it was belt slip. But no amount of "foot slogging" cured the trouble. So I shut off the engine. On trying to start up with a run, I found that the belt and chain to the engine sprocket were going round all right with the control lever in top notch (the machine is fitted with a Mabon variable gear), but there was no movement from the engine, and all the time the machine was being wheeled in top gear there was not the slightest movement of the engine sprocket on the magneto side, and the magneto chain was stationary. I thought that something might have given way internally, or that the key on the engine-shaft had broken. Anyway, we pushed the machine (in gear) two miles to the county town, garaged it, and went by train to our destination. On the second morning after, I returned for it. With a little difficulty I took the nut and spring washer off the engine-shaft with a view to examining the key, and on rising from my cramped position accidentally fell against the machine, causing it to move a few inches, when hey, presto! the engine started to "sigh" as the piston rose on the exhaust stroke. That was good enough for me, and after wheeling the vehicle up and down the garage for a while to make sure that I was not deceived, hastily replaced the spring washer and nut, and got on the road. I did the remaining twenty-six miles non-stop (except once to change the plug) in just under an hour and a half in spite of a terrific wind against me all the way. I do not think I have left anything out which might form a clue, and if someone will clear up the "mystery" for me I shall be grateful.

A. CALDWELL DALTON.

MAKERS AND PROMPT SERVICE.

Sir,—More than five weeks ago I sent a broken valve and guide to one of the largest motor cycle engine makers in the country, and, to avoid any possible chance of mistake, I sent also the unbroken valve and guide as patterns. I also enclosed full particulars and stamped envelope for reply as to amount of remittance.

After waiting a week I again wrote, explaining the vital need of my machine. I then received a "permit form," which was promptly returned by express letter post.

Another week elapsed before I was furnished with a statement of cost. This was remitted, with extras for parcel express post, per registered letter.

After further considerable delay a pair of valves arrived suitable for an 8 h.p. engine (mine is a lightweight), and by separate post the next day a guide to suit the 8 h.p. valves. In the meantime the makers still retained the parts sent them as patterns, without which, even if the valves and guides sent had been of correct size, my machine could not have been used. Having returned the parts (useless to me), I have since received the parts sent as patterns with a letter stating, "Sorry for delay, but will not be able to supply 'for some time.'"

Thus, after five weeks, I am told that which should have been communicated to me at the outset, and before they raked in my money, which, by the way, seems to have been the only businesslike action of the whole transaction.

Of course, the moral is, if one requires prompt service avoid "some" makers, advertise through your journal for the parts, or deal with an outside supply firm. E.B.S.

BOOKS FOR MOTOR CYCLISTS

HINTS AND TIPS FOR MOTOR CYCLISTS.

A valuable collection of useful "winkles" and items of information concerning the running, management, and repair of motor cycles. Price 2/- net. By post, 2/3.

TRACING TROUBLES.

Motor Cycle Faults, Their Identification, and Their Remedies Fully Explained. Price 2/- net. By post, 2/2.

Obtainable by post (remittance with order) from

ILIFFE & SONS Ltd., 20, Tudor Street, London, E.C.4
or of leading Booksellers and Railway Bookstalls.

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

A Smoky Flame.

? I am engaged on work of national importance, and use a motor cycle to go to my work. I burn carbide for lighting, but get very poor light at present. The flame smokes a good deal, and soon goes out. I have tried washing it in paraffin, but get worse light than before. I have also fitted a new burner and tested the tube for leaks, but with no better results. Is there anything I can mix with the carbide or put in the water to improve the light?—F.J.C.W.

The trouble of which you speak is rather curious, and the smoky flames from the acetylene gas would lead one to suppose that the design of the burner is incorrect, and that more air is required with the gas. The velocity of the gas issuing from the burner is evidently too low—perhaps you are using too coarse a jet—but having changed your burner we are surprised that you do not get some improvement. Peroxide of hydrogen (2 to 3 ounces to each pint of soft water) is said to improve the light.

Theory of Spark Timing.

? Respecting the valve timing diagram on page 395 of *The Motor Cycle* for October 31st, will you kindly explain why the firing point is 9.2 mm. from the top of the compression stroke? It seems to me that it ought to be a shade down on the firing stroke, and not as shown in the diagram, which, in my opinion, would not allow the piston to complete the compression stroke. I have nearly all your booklets, but I cannot quite understand the theory of spark advance.—R.K.K.

The diagram is quite correct. The spark occurs before the end of the stroke in order to allow the mixture to become properly ignited by the time the piston reaches the top dead centre. You will understand that when the spark is fully advanced, the engine is turning over fairly rapidly. The time occupied by the piston in travelling the last nine millimetres is something under one-three-hundredth of a second, at the moderate engine speed of 1,000 r.p.m. The amount of advance depends largely on the phenomenon of "flame propagation," which is the rate at which the mixture burns. You will see, therefore, that if the mixture was not ignited till the top dead centre on compression, power would be lost because the piston would not receive the full benefit of the explosion.

Trouble with Sidecar Machine.

? I have a 6 h.p. motor cycle and sidecar, which I have ridden about 1,000 miles, and now it has begun playing me tricks.

After running a mile or so, it starts missing on one cylinder when pulling on top gear or going slowly on second, but seems all right when going fast. I found that the contact breaker points were too wide, and have closed them, and now with the spark retarded I do not notice it so much. Can you give me any reason for it? I have cleaned the cylinders, but find the machine has less power than it had after I had ridden it five hundred miles; the power gradually gets less. I can find no trace of leakage. Do you think the plug points are too close or too far apart? I have the Master plug, and when I take it out I can see it fire, but it does not seem to catch on when in the cylinder. It is the front one that misses. Can you also tell me why it is that when going round a slight bend in the road the outfit feels as if it will turn over, and I have to ride with the saddle high on the outside to be at all comfortable? I find the driving wheel and the sidecar wheel are exactly straight, but not level; the sidecar wheel is about a foot in front of the driving wheel. It is very uncomfortable, and I should be glad if you could give me a tip.—E.B.W.

We should advise you to try setting the plug points rather farther apart. Also make sure that there is no obstruction in the petrol supply, of air lock in tank or pipe. Apparently your sidecar is not lined up correctly, or it may be that you are unaccustomed to sidecar driving. We should advise you to obtain a copy of "Motor Cycles and How to Manage Them," 1s. 10d. post free from our publishers, Messrs. Iliffe and Sons Ltd., 20, Tudor Street, London, E.C.4.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication.

ILIFFE & SONS LTD.

Two-stroke Valve Timing.

? I shall be obliged if you can tell me what is the correct fraction of each stroke, during which the inlet and exhaust ports respectively are uncovered by the piston of a two-stroke engine; in other words, the correct timing of such an engine.—R.S.T.

The port areas and timing are obtained by trial, and no definite data have been published on the subject as yet; each firm has its own design. Generally the exhaust opens at about three-fifths of the piston travel and the transfer port at four-fifths, each port being about one-fifth the stroke in depth. Some makers time their transfer ports to open at 25° crankshaft rotation after the exhaust opens. This matter is gone fully into in *The Automobile Engineer* for May and June, 1918.

Cones Working Loose.

? Will you tell me why the cones which screw into the hub of the front wheel work loose and unscrew themselves? I was on the road a few days ago, and travelling at a moderate speed, when I noticed that one cone had come right out and the wheel was riding on the spindle which runs through the hub. I screwed it up again and tightened it with a hammer and punch, but after riding about five miles it came out again, so I punched it tightly again and turned back home. After a few more miles the other one on the opposite side came unscrewed, and I had to push the combination home. I have written and had a reply from the makers, but they can suggest nothing, and say they never heard of such a thing happening before. The lock nuts come unscrewed.—C.B.

The trouble is almost undoubtedly due to your not screwing up the spindle nut sufficiently tightly to grip the cone. If there is insufficient grip on the cones, washers should be inserted between the fork ends and the cones so as to enable the spindle nuts to exert pressure on the cones.

RECOMMENDED ROUTES.

FRIDAY BRIDGE TO HARROW.—G.G.

Friday Bridge, March, Chatteris, Somersham, St. Ives, Hilton, Eltisley, Waresby, Pottton, Biggleswade, Baldock, Stevenage, Welwyn, Hatfield, Potters Bar, Barnet, Finchley, Church End; here take the right-hand fork and go through Hendon, cross the Edgware Road, and then go through Kenton to Harrow-on-the-Hill.

The Future of the Two-stroke.

THERE is no need to dwell upon the great possibilities of the two-stroke engine, which scores over the four-stroke in the three essential points of torque, simplicity, and longevity, and a more useful purpose might be served by reviewing the points on which it falls short of the four-stroke—useful because these shortcomings, or rather the prospect of their elimination, largely decide its possibilities.

We have had experience of every well-known two-stroke engine that has been placed on the road by British manufacturers, and though some are better and some worse than others, all of them possessed the same minor peculiarities to a more or less marked degree—peculiarities which, though hardly noticeable to a rider accustomed to the breed, are nevertheless sufficient to stand as stumbling-blocks in the way of its universal popularity.

First, there is the trouble of four-stroking at certain throttle openings, brought about by the present system of governing the engine by varying its volumetric efficiency. At small throttle openings, let us say, the engine four-strokes or eight-strokes; this is because the reduced charge drawn into the crank case, owing to the closing of the throttle, is insufficient for an explosion at the given mixture, and the mixture has to adjust itself during the scavenging processes ere an explosion can take place. If the throttle air be left in one position, and the speed regulated by means of a small, sensitive decompressor, no missing fire occurs, and though this system is wasteful and obviously wrong, it is, nevertheless, often the most comfortable. It would seem, then, that the whole method of governing the engine by throttling the charge between the jet and the crank case is wrong in the case of the two-stroke, and it is not unreasonable to think that some better method might be adopted. There are ways of governing the speed of an engine without varying the mixture or the volumetric efficiency—ways that

need not be wasteful if properly applied. We believe that, if some more efficient and perfect way were devised for controlling this unit, many of the peculiarities of the breed would automatically disappear, or at any rate come within range of elimination. Noise and extravagance in fuel consumption are directly connected, the irregularity of noise being the chief cause of offence in this type. Obtain an even exhaust and the problem of silencing is purely mechanical, the two-stroke engine being inherently a quieter engine than a four-stroke having the same number of explosions. The high petrol consumption, often experienced in two-strokes, is all due to the compromises that have to be struck, and most of these compromises centre round the system of control now employed.

One cannot apply four-stroke tactics to the two-stroke: let us get right away from these, realising that the engine is an entirely different breed; and having realised so much it may become clear that its peculiarities are not necessarily inherent, but rather the result of attempting to use four-stroke methods to which we had become accustomed.

The Aviation Section.

THE four-page section of this journal, which from April last to the end of 1918 was devoted to Aviation matters, has now served its purpose, which was fully set forth at the time of its introduction. Therefore, in spite of its undoubted popularity with many of our readers, we feel that the time has come when it should be discontinued. This decision has been reached with a certain amount of reluctance, but the call of purely motor cycle matters on the space at our disposal is daily becoming more and more insistent. This does not mean that flying will cease to find a place in our pages, for we shall continue to publish articles on this interesting subject at frequent intervals; in fact, we have several such articles in hand at the present time.

THE LOCAL AGENT.

Some Notes on
Agents who Justify, and
Others who do not Justify,
their Position.

ONE of the most complex questions of the motor cycle industry is the problem of the agent—a problem which, I think, will become more acute in the near future, and demand more attention than it has hitherto received.

Distribution comes next in importance to the item of price, and it is indeed bound up in it very closely at the present time, when abnormal conditions of labour and material supply obtain and each acts and reacts upon the other. Up to the time of the war, the prices of new machines were in some degree compatible with the standard of living, and were in a reasonable proportion to the average earning capacity of the normal man, and the market bore a favourable proportion to the supply. The manufacturer did not trouble his head about distribution—that was generally left to the agent.

Now there are agents and agents. There is the man with a musty back street shop who sticks a machine in his window and combines the agency with the business of jobbing repairer. He has no interest in the machine he sells any more than the grocer has interest in the packet of tea he hands you. He never advertises either in the technical or local press. The machine is shown at a disadvantage, dusty, tarnished, and scratched amid tins of oil, repair outfits, and the hundred and one etceteras of the motorists' cheap-jack. He does not enhance the reputation and the dignity of the maker, and the latter does the selling, unconsciously perhaps, but nevertheless truly. When a machine is sold, that is the end of it so far as the "agent" is concerned.

Organised Business.

Is it not now a recognised fact that "service" is the keynote of successful motor cycle trading? Look, then, at the other side of the picture. This is an agency—something more than a dirty shed with "agent" in enamel letters on the unwashed windows. This is a spacious showroom in a busy thoroughfare—not very big, perhaps, but well laid out for the business for which it is intended—a light airy room, nothing over-elaborate, with perhaps a dozen machines ranged accessibly round, a courteous salesman, judicious advertising, reasonable profits, and good "after-service" leading to pleased clients: benefits to agent and maker, resulting in increased sales—*made* sales, not casual purchases.

One of the first reconstruction problems I therefore maintain, in the interests of business prestige, is the abolition of promiscuous agencies without investigation. The manufacturer must work directly hand in hand with his accredited agencies, so that "real service" may be maintained.

An example of a motor cycle dealer's shop, showing what can be done to make a finished and businesslike display in a limited space.

Another point which it is in the interests of manufacturers to take cognisance of is the dog-in-the-manger type of agency, wherein the proprietors seek to corner the local agency for the whole of the motor cycle market. They may have the sole district agency, secured on small contracts, for, say, half a dozen machines, but they do not want to sell them all. They perhaps have a good proposition in one machine, and merely hold the others, generally somewhat similar machines, so as to keep them out of the hands of other agents and preclude any competitive selling. In some cases I have known agents do this and dispose of the surplus machines to sub-agents outside their area.

Then there is the firm which grabs all the available agencies and sells on stock alone, thus it has no opportunity of pushing any particular make, and, as is the case with the majority of back street agencies mentioned before, its advertising allowance from the manufacturer is looked upon as extra discount, and treated as such.

Competition is going to be keen—all extraneous sources of leakage must be stopped, and that means the abolition of the "dabbler" who, because he includes "motor cycles" on his notepaper, claims to be a trader. The wholesaler or concessionaire, too, is a doubtful quantity. There are but few of these, but there is the tendency for the maker to endeavour to do his business through fewer channels. If direct agencies are once established on a proper footing, the need for these people will vanish. Their only hold is the fact of financial resource.

Now the policies of even our biggest motor cycle makers are not as broad and far-seeing as is desirable. Insufficient attention is given to the question of replacements and spares, and those other points which come under the heading of "service." The maintenance business must be treated as being of equal importance to the new machines, and manufacturers must altogether take a closer personal interest in their agents and their requirements. General or wide area agencies I do not advocate unless a thorough system of sub-agencies covers the whole area controlled by them.

With fixed makers' prices, it makes no difference to the user whence he obtains his machine so long as the seller is in the vicinity and can be looked to for the ready supply of replacements and any adjustments that may be required which are beyond the ability of the owner.

MASCOT.

Occasional Comments

The Spring Frame Lightweight.

IN a recent issue "Wharfedale" underlined the sensation of confidence imparted to the rider by the steadiness of a heavy mount, and described how the vibrations of a lightweight put the wind up him on rough going. I have repeatedly written in a similar strain, but I think the time has come to introduce an important modification into such statements. A rigid frame lightweight gives one the impression that its frame is eternally on the verge of fracture; but it by no means follows that a spring-framed lightweight creates this illusion. I analysed my own impressions in this respect pretty thoroughly in 1915 with the aid of a push bicycle, a rigid James two-stroke, a spring and a rigid $2\frac{3}{4}$ h.p. Douglas, a rigid $3\frac{1}{2}$ h.p. B.S.A., and a spring $3\frac{1}{2}$ h.p. A.B.C. In the endeavour to eliminate mere fancy, I reflected that I had never broken the forks or frame of a push bicycle or of any motor bicycle less than $3\frac{1}{2}$ h.p.; and so decided that my sensations of insecurity were simply due to imagination, stimulated by the jiggety progress of a stiff machine on rough roads. Contrasted rides on the mounts specified above soon proved that my nervousness was nothing but the product of imagination. All the rigid-framed machines dithered and shook me when ridden fast over bad going. Realising the vibration to which the metal was subjected, I began fancying what would happen if a tube collapsed: and the consequence was that I was always a little uncomfortable in mind when bestriding the push bicycle or any of the three rigid motor bicycles, though in sober fact there was not an atom of danger with any of them.

Spring Douglas v. Rigid Douglas.

FROM these conclusions I went on to make comparative tests of the spring and rigid frame Douglas machines. I have been a Douglas enthusiast for many years, and took the spring frame Douglas and tried it out in fast long-distance work against rigid and spring frame machines of $3\frac{1}{2}$ h.p. It emerged most triumphantly. It held the road so well that it neither tired me physically nor set the nery part of me dreaming of broken tubes. Of course it is not so fast nor so good a climber as a rigid $3\frac{1}{2}$ h.p.: but on runs where extreme speed is not desired I give it my preference against any rigid $3\frac{1}{2}$ h.p. machine. In other words, the addition of a spring frame perfects the $2\frac{3}{4}$ h.p. type for medium speed touring, in my opinion, and gives it a vanage over the rigid $3\frac{1}{2}$ h.p. class. Therefore it is but a short step forward to say that when at last we get sprung "babies," they need evince no drawbacks other than their lack of speed. The real trouble will be that spring frames are as yet so intensely ponderous. When a designer comes out with a spring frame, he usually

adds about 40 lb. to the weight of his jigger. If the engine develops 8-12 b.h.p. (as some 500 c.c. engines do), 40 lb. is a mere fleabite: but with a power unit of 200 c.c. or so, an extra 40 lb. is a real drag. In spite of the doubting Thomases, I cannot help thinking that an era of lighter metals is dawning, and that we may live to see spring-framed lightweights which will not weigh more than 120-150 lb. Subject to their limited speed range, such machines will enjoy a tremendous demand. At present we stand between the Scylla of an uncouth 2 cwt.-3 cwt. machine, which is delightful to ride but a terrible incubus to weakly owners until it is actually on the move: and the Charybdis of a 150-180 lb. machine, which is docile in the garage but a veritable instrument of torture on really bad roads.

Low Speed Range.

"WHARFEDALE" evidently thinks that low speed range would kill the "babies," if their other defects were eliminated. Of course, the average pre-war motor cyclist was a husky sort of person who loved speed: and a creepy little 'bus with a maximum of 30-35 m.p.h. on the level would not satisfy him. Nevertheless, there are thousands of potential buyers for whom speed has no attraction of any kind, and thousands more for whom it is not essential. After all, "Wharfedale's" despised 20 m.p.h. lightweight is considerably faster than the push bicycle, the governess cart, the farmer's trap, and my lady's Victoria. The motor car has stiffened up the conventions of travel, but there will always be thousands of people who cannot buy motor cars. At the present moment there is a difference of over £30 between the price of a $2\frac{1}{2}$ h.p. lightweight and a $3\frac{1}{2}$ h.p. roadster, whilst the latter is so heavy that many men and women will not buy one, though they can afford it. If the trade can ever offer a genuinely comfortable and reliable lightweight at £15-£25 less than the standard roadsters of the day, the sales of that lightweight will equal the sales of the roadster. But until lightweights are comfortable, neither their handiness nor their cheapness will carry them through, for the buyers to whom they appeal set a very high value on comfort. We cannot overlook the fact that discomfort has practically slaughtered the push bicycle as an instrument of pleasure. A few years ago thousands of people went out cycling whenever the weather was propitious. Then the pot-hole and the tramline and the dust cloud came along, and the push bicycle was relegated to the status of an umbrella—a necessary evil under certain deplorable circumstances! So I say to the trade, "Make your lightweights comfortable, and they will sell, even if they never become as speedy as I have rashly ventured to prophesy!"

The Future of Surplus Government Machines.

Suggestions for their Disposal.

THERE are many motor cyclists who are inclined to think that sooner or later they will be able to make extraordinarily good bargains in the form of the purchase of surplus Government machines from among the many hundreds of thousands that are bound to come upon the market. I am afraid that these people, or at any rate the majority of them, are doomed to disappointment, but I am very strongly of the opinion that their disappointment would have been even more serious had they been able to carry out their intended programme. Probably a certain number of machines will, so to speak, leak on to the market from various sources. Among these there will be a few uncommonly good bargains. On the other hand, there will be a big percentage of "duds" hardly worth carting home. Motor cycles that have seen active service have in most cases had a very rough time. They have been subjected to stresses, the consequences of which, even if not apparent, may have been very serious. We all know that metal may be reduced by repeated shocks to a state which will, in the near future, result in a sudden fracture, though at the time no flaw is apparent or actually in existence. This is the sort of risk that must be run by the bargain hunter.

A Government Disposal Board.

As regards the great bulk of the Government machines which will presently become surplus property waiting disposal, there is not the slightest likelihood of any very extraordinary bargains eventuating. All that the motor cyclist can expect from them is reasonably good value for money. They will appeal to the man who cannot afford a new mount, but they will not appeal as being better value, but merely as being lower-priced.

The whole subject of surplus Government property has been muddled for years past. Not less than three years ago, the manufacturers concerned began to bestir themselves in order that their interests should be reasonably protected when the time came. At first the War Department talked about constituting a committee to go into the matter. This committee never eventuated. Later on, an organisation was formed under the name of the Surplus Government Property Disposal Board. This was a collection of very worthy individuals of whom only two or three at the most had any intimate knowledge of any class of motor vehicles. So far as I am aware, not one of them had any special reason to be well informed about the motor cycle trade. The Board was created by the Ministry of Reconstruction, which is itself only an Advisory Department without full power of executive action. Subsequently there was talk of transferring the Board from the Ministry of Reconstruction to the Board of

Trade. The only result of the talk was that the Disposal Board got thoroughly muddled as to whom it was and what it was for. It became apparent that, even if it succeeded in framing a report that was worth reading, there was no means of deciding whose business it was to read it. Probably there are many Government reports that are never read by anybody in authority, but it is a *sine qua non* that every report shall be addressed to somebody who is *supposed* to read it. The Surplus Government Property Disposal Board was faced with the prospect of issuing a report which would not even have an effective circulation of one, and therefore decided, with more wisdom than it had previously shown in most of its previous deliberations, not to issue a report at all.

The Interests of Manufacturers.

The manufacturers, who had been doing their best to enlighten the Board as to the gravity of the problem and the best method of solution, consequently found they had been wasting their time. They, however, were not altogether discouraged. They went on hammering, and presently the Government decided that the whole subject of the disposal of surplus property, to whatever department it might belong, should be referred finally for executive action to the Ministry of Munitions, presently to be turned into the Ministry of Supply. Having got thus far, it looks now as if things would go further without very much more delay. Unless I am altogether misinformed, a really strong committee has been going into the question, and has decided that the disposal of all classes of motor vehicles, including cycles, has got to be organised by a specially constituted branch of the Ministry. Again, unless I am misinformed, the executive of this branch will consist of people who have had every reason to study the subject carefully and even anxiously. This executive will be assisted by an advisory committee, and I should be surprised if, on that advisory committee, the interests of the manufacturers are not represented.

Goodwill.

Fortunately, in this particular case the interests of the manufacturer are not really out of line with the interests of the motor cyclist, with the exception perhaps of the speculative bargain hunter. The reason the manufacturer must certainly be considered is that his goodwill depends on the performance of the machine he has built. In fact, the goodwill of the whole British motor industry is more or less dependent upon the performance of any British machine. If thousands of British-built motor cycles went out to the Empire Overseas and strewed the roads with

The Future of Surplus Government Machines.—

broken remnants during their first few months of renewed existence, we should have hundreds of thousands of people cursing the names of the makers of those machines, and almost as vigorously cursing the name of the British industry as a whole. Now, when continuous employment for the working classes is the great problem of the day, the country cannot afford to have this kind of thing happening merely because there might be a few among the many buyers who would have reason to pat themselves on the back for having got something good for next to nothing. More consideration must be bestowed upon the inexperienced motor cyclist to whom this second-hand surplus Government machine represents his first experiment, upon which all his opinions as to the pleasures or miseries of motor cycling will be based. We do not want to kill his enthusiasm at birth, but rather to make him into a keen motor cyclist who will presently want something better than a second-hand machine.

The Question of Price.

We must consider the interests of the Government, which must, if it be sensible, try and work out some scheme which will enable it to get decent prices for its surplus goods. There is no reason why the Government should start making people presents of valuable machines. There is equally no reason why it should spoil the reputation of the stuff it wants to sell by letting a part of it go out more or less unfit for use and fall into the hands of people who will warn others against making the same mistake. Thus, the majority interest is all in favour of the adoption of some general scheme under which none of the Government machines, except a few stragglers, will be sold until they have been thoroughly overhauled by people who are interested in making them absolutely reliable. Evidently the people most interested in this are the manufacturers themselves, because their reputations are at stake. Thus, the chances are very much in favour of the Ministry of Munitions working out a plan under which all the surplus bicycles will first of all be offered to their manufacturers for repair on reasonable terms, subject to the proviso that, when they are repaired, the manufacturers will guarantee their condition. This guarantee will be worth a good deal of money. People who cannot quite trust their own judgment will be prepared to pay substantially for it. Even the man who knows all about motor bicycles will appreciate that the makers' guarantee is worth something to him, because it means that, if he has any trouble, the maker must recognise the machine as one of his own, in the performance of which he is interested. If, on the other hand, the machine had been auctioned just as it came back from the Front, the chances are that, when trouble occurred and the maker was appealed to, he would ask for the number of the machine, and, on being told it, would say that this machine had passed through experiences of which he knows nothing; had probably been inefficiently repaired, and most likely had been so altered that the regulation spare parts would not fit it. He, in fact, would be very much inclined to put all possible difficulties in the way of getting the machine repaired. At the best he would not be much interested, but would prefer to disown responsibility.

Upsetting the Sale of New Machines.

Having got the machines repaired and guaranteed, the next step for the Government will be to sell them. Here again, if the Government wants a good price, the best plan will almost certainly be to work through the manufacturer and his agents. The manufacturer will want to keep the price up to a proper mark corresponding to the value of the machine, because, if it drops too low, it will upset the sale of his new products. Thus, he will do his best to help the Government to realise the full market value of its property. This process may not be quite to the liking of the bargain hunter, but again I must repeat that the bargain hunter is not the person for whom the Government particularly wishes to cater. The general interest of the public must be considered first. The people who want second-hand machines may, if they like, wait for the Government stuff to come through. They will then get their money's worth. Meanwhile, if they can afford it, they will get their money's worth equally well by purchasing new machines. If they cannot afford new machines they will probably be just as well advised to purchase discreetly on the ordinary second-hand market if they are well enough informed to do so without serious risk. This is the whole position. It is not full of wonderful possibilities, but, unless I have gauged the chances altogether wrongly, the problem will be dealt with on safe rather than on brilliant lines, and the prices at which surplus machines will be made available will be simply those that represent ordinary market value and neither more nor less.

Motor Cycle
Movement.

Second Series:

Comments of
Designers and
Others well-
known to Motor
Cyclists.

A Third Selection
Next Week.

From Mr. Granville E. Bradshaw, Designer
of the A.B.C. Motor Cycle.

THE question of reconstruction is one of vital importance to the motor cyclist, the production departments, and the designer; and, in my opinion, the motor cyclist should come first.

There is an enormous gap, stored with knowledge, between the years 1914 and 1919, and, I think, the motor cyclist should benefit by it.

The production man's idea of carrying on with improved 1914 designs for 1919 is surely a fallacy, as is also the old idea of a machine built up of additions, year by year.

To sit down for a few weeks and thoroughly thrash out the matter, using all the knowledge now available, will, I think, result in better machines, and comparatively cheaper production.

Personally, I do not intend to let the public have anything but a complete job, well balanced in all details of efficiency, design, and manufacture, a machine thoroughly tested in every way, and produced by methods that will give the rider all the value for his money that he ought to have—and I am pleased to say that this is now practically achieved.

I wish readers of *The Motor Cycle* all the pleasure possible on their new mounts, together with good roads and petrol in abundance in the year just commenced.

From Mr. Duncan Watson, Managing
Director of the Harley-Davidson Motor
Co., Ltd.

RECONSTRUCTION is paramount at the moment; it dominates political propaganda and embodies social, industrial, and commercial promise and prospect; it fills the air with speculation and foreshadows evolution that will carry us into purer elements, and breathe into our national being a spirit of more profound and generous emotion for the amelioration and up-lifting of society.

We have passed from dreams to active reality. Dawn has awakened us with dramatic suddenness, and we are rubbing our eyes and asking whether it can all be true; is it fact or mere phantasy? Everything whispers, "What of the future?" The tides echo the answer, "What you choose to make it, and you must seize opportunity while it serves."

Such is the message ringing out to every industry, hence speculate we must, whether we choose to or not, and wise is the man who can correctly forecast the future of our industry. Whether rider, agent, or manufacturer, all must contribute their respective quota towards shaping its course, and as I pen these lines the future is already taking form.

My personal view is that the direction most indicative of future success will be found along the lines of elegance, utility, and efficiency. Legislation will unquestionably play an important part, and price also will play its part. The trend of legislation will largely determine the value of the sovereign as applied to manufactured goods, whether its artificial value is to remain or rapidly gravitate towards the normal.

Standardisation and increased production will depend largely on popularity and demand for respective models. If either of these dominating factors be eliminated or abrogated, popular prices as an inducement for recruits to motor cycling will be delayed indefinitely. The survival of the fittest will be demonstrated with relentless exactitude, and efficient service will count even more than design. To that end the industry must organise to progress as it should. There are indications that the motor cycle industry for the next few years will undoubtedly boom, and manufacturers must remember that success is even more difficult to carry than adversity, and peace hath her defeats no less than war.

There is no finality in the manufacture and design of a motor cycle; nothing is now done so well as it can be done.

These facts must remain uppermost in the policy and mind of all manufacturers. The lessons of the war, unless applied, or even misapplied, may bring disasters

in peace. Let us with one accord lay these warnings to heart, and, with persistent reiteration and stimulation of our trade journals, have them constantly brought to mind—"Lest we forget."

From Mr. T. W. Blumfield, Managing
Director of Abingdon-Ecco, Ltd.

I BELIEVE it is well-known that machines which give satisfaction in this country may not be satisfactory under the more exacting conditions abroad, which must at times be appalling, and make one marvel that any machine can stand up very long.

It would appear, judging from our own correspondence and the letters which have appeared in your Correspondence columns from Colonial subscribers from time to time, that all (or some) of the following points in design must be embodied in machines for use in our Colonies:

1. Increased ground clearance. We have frequently been asked for a minimum of 7in., and one customer recently asked for a machine with a 9in. clearance.
2. Increased diameter of wheels and larger section tyres. 3in. appears to be regarded as a minimum.
3. Stronger rims and spokes.
4. Improved mud-guarding, with greatly increased clearances for tyres.
5. Frames must be sprung at the rear.
6. Longer steering heads with larger fork stems, having increased bearings, and provided with dirt-excluding devices and screwed-down grease caps for lubrication.
7. Larger twin-cylinder engines. Probably up to 1,100 or 1,200 c.c. capacity, with relatively low compression, and increased bearing surfaces everywhere.
8. Automatic lubricating system to the engine. In my opinion, the system which will eventually survive is one in which the oil is delivered from the engine oil pump through adjustable sight feeds, and not one in which the oil circulation cannot be observed from the saddle. I believe also it will be desirable to have the old reliable hand-operated oil pump as an auxiliary.
9. Detachable hubs may be regarded as desirable, perhaps, but not essential.
10. Abolition of the front rim brake.
11. Some form of positively locking the handle-bars as a preventive against twisting. All the foregoing features tend to increase weight and cost. I think a point will shortly be reached when the

Mr. Duncan Watson

Opinions.—

latter will be so high that a reaction will occur in favour of three (or four) wheel cycle cars, if not for Colonial then certainly for home use.

While there is hardly anything on the road so lively and responsive as a big twin outfit properly tuned, the sidecar combination has, I consider, serious inherent defects. In wet weather its driver becomes covered with road filth up to his knees, even on the best mudguards machines, and his condition on dry, dusty roads is nearly as bad. Special garments must be worn, and these have to be removed if one enters any house, office, or hotel, where personal appearance has to be considered.

On the three (or four) wheeler runabouts, one has much better protection from bad weather and dust. The screen, hood, and body combined enable one to drive in ordinary clothing and to keep appointments in presentable condition without stripping off filthy overalls. Further, greater comfort is obtainable, resulting from the improved seating accommodation and better springing, which has hitherto been much better than that provided on the two-wheel machines, and these advantages, I think, will surely convert many owners to three (or four) wheelers instead of two.

On the question of cost. I think a comfortable three-wheeler, at any rate, could easily be placed on the market at a price certainly not exceeding that of the more elaborate sidecar combinations.

Running and maintenance expenses will probably be rather less in the case of a three-wheeler than with the combination. I should not be surprised to see eventually single-seater three-wheelers in use by professional men, commercial travellers, etc., with just sufficient accommodation to carry a few samples (or their equivalent).

From Mr. Osborne de Lissa, of the M.A.G. Engine Co., Ltd.

THERE is, in my opinion, a fine future before the motor cycle industry, but the best machines will be more in demand, due to the increased knowledge gained by all who have had to use motor cycles on Active Service, and who have learnt that only the very best will stand up to the severe conditions imposed.

Frames and forks have caused manufacturers to put on their thinking caps, they having learnt by experience—bitter in many cases—what a machine is asked to stand under Colonial conditions when previously no amount of talking had much, if any, effect.

In this country also motor cycles will be asked to stand up to much more severe tests than in pre-war days, owing to the bad roads in many districts, and this will no doubt indirectly improve their reliability in the Colonies.

As with others, the M.A.G. engine has been still further improved, and I am

Mr. Osborne de Lissa.

hoping we shall soon be permitted to supply engines, which have given excellent results in France, Italy, and Russia, where they have been used by the military authorities of those countries.

The manufacturers of the M.A.G. have also been engaged on the production of aircraft engines, both of the fixed and rotary types, and have gained much valuable experience thereby, and, in addition to the well-known motor cycle and cycle car engines, the firm now manufacture four-cylinder automobile engines from 10 h.p. to 60 h.p., and also engines for farm tractor work.

I look forward to the reopening of Brooklands, when the future performances of the various makes may be compared with their past records.

From Mr. Jas. L. Norton, of Long Stroke Fame.

A PART from a few freak designs, I do not anticipate any serious or startling innovation in post-war motor cycle engines due to the influence of aero practice or design, the mysterious elements of which we have been hearing so much about, and the efficiency of the aero engine being purely due to the more general recognition and application of certain fundamental laws or principles, which previously the majority of designers ignored.

This latter, and the wider knowledge of metals and their treatment, with the value and necessity of accurate workmanship being more fully realised, will have the effect of raising the general efficiency average of motor cycle engines.

The extreme methods of aero engine production under the A.I.D. can never apply profitably to a commercial motor cycle proposition, although the intensive and scientific methods of production necessarily enforced upon those firms previously ignorant of such cannot but have a beneficial effect upon the industry as a whole. This will be felt in the marketing of machines of greater capacity power and economy at a smaller (proportionate) cost.

The demand for motor cycles for two or three seasons will be scarcely more than met, after which competition will undoubtedly become severe. The prosperity of the motor cycle industry will depend largely upon its workers, as indeed does the welfare of every industry. At no time in our nation's history has the need for commonsense and sane thinking among the workers been greater than to-day (thank goodness for some thinkers among them), when so many appear to be blindly following the criminal butchers who are out to kill the goose that lays the golden egg. Productiveness, which means prosperity.

Ours would be a happier and even wealthier country if Labour's slogan was "Unlimited output."

Mr. J. L. Norton.

From Mr. Georges Funck, A.M.I.A.E., the Consulting Engineer.

I BELIEVE it is the best for the user and manufacturer to follow an outline of policy on the basis of a classification. We may conveniently place the machines under two headings:

(1.) *Solo machines*, i.e., those machines used mainly for solo riding.

(2.) *Passenger machines*, i.e., those machines used mainly for carrying a passenger besides the driver.

These two main classes may each be sub-divided into two:

(1.) *Utility machine*, i.e., machine used mainly for business purposes.

(2.) *Sporting machine*, i.e., machine used mainly for pleasure riding, racing, etc.

In my opinion, the solo machine for business purposes will be the lightweight, either of the two-stroke or four-stroke type. Simplicity and reliability will be one of the first considerations. Two speeds will be required if for hilly districts. The mudguards will require more particular study by the manufacturers. No plating should be used, and a non-rusting process applied to the exposed parts, while for the nuts and bolts probably the stainless steel will be the best material. Electric lighting will be an essential part of the machine. This lightweight machine would be particularly suitable for journeys up to forty miles, while for longer journeys a slightly heavier machine up to 4 h.p. would probably meet the requirements of the majority.

With regard to the solo machine for sport, competition, etc., speed and reliability will come first, next may come appearance. In any case, the manufacturer will not be in a position to standardise so easily, as he will be asked for slight modifications, different gear ratio, etc., to suit individual requirements. Probably the day of this kind of thing has gone.

As to the passenger mount, the twin-engine machine will be in the forefront, and 5 h.p. may be considered to be the satisfactory minimum. The four-cylinder will probably be the ideal sidecar machine in combination, or with shaft drive. All machines will have to receive far more effective mud-protecting devices. With the passenger machine this defect is the more pronounced on account of the well-protected position of the passenger.

I cannot help thinking that, particularly on account of this point, the sidecar passenger combination will ultimately be replaced by a passenger machine of similar price and necessary upkeep, but affording to the driver the same protection and comfort as to the passenger. The difficulty, however, will be found not so largely in the suitable design but in the fact that the sidecarist is mostly the natural product of the solo rider, and, therefore, adheres naturally to his familiar motor cycle.

Mr. Georges Funck.

Opinions.—

From Mr. S. L. Bailey, the Douglas Exponent.

THE cataclysm overwhelming Europe has been stemmed—the greatest sacrifice of men and metal made—but the price of it is still somebody's debt. Such is the position to-day.

Reconstruction and demobilisation stare us in the face, turn which way we will. Yet, despite the past four years' training of our minds in great events, great things, and great numbers, is there one amongst us that can comprehend in their fullness the two issues before us? I fear not. Each will have to work his hardest in his own particular little sphere to attain the desired end—to make Britain worthy of the British—industrially, particularly as nationally we have attained our zenith.

We of the motor industries have a big task before us, if we wish to see that we are no worse off commercially than nationally. However, when the huge problem of munition making first confronted this

country it was the motor industries that provided the solution of the problem, and they were quick to recognise that only by immediate reconstruction could they hope to prevent the recurrence of the problem. The reconstruction of to-day is no less, and, what is more important, no greater, than the reconstruction of that day, and the world may be agreeably

Mr. S. L. Bailey

surprised—disagreeably perhaps in some parts—to find us prepared to contest a commercial warfare equalling almost the conflict that has for us so recently and victoriously ended. Motor cycle manufacturers are still aware of their positions, and are working night and day reconstructing, but they are still labouring under war time legislation. This heavily fetters them and places many obstacles in the way of progression. Once freed or even relieved in this direction, developments will proceed apace. I have hopes that the early new year will see the repealing of many of these laws, that were made to assist the industry in the making of war material, and also the making of new laws to protect the industrial life of the country.

From Capt. Geoffrey Smith, M.B.E., R.A.F., who will shortly resume Editorship of "The Motor Cycle."

WHAT of the future? That is the question of the moment. Thousands of enthusiastic motor cyclists, expectant of realising their ideal of a road-worthy machine at a reasonably low figure, impatiently watch the announcements of new models. This transition stage, during which manufacturers are hurrying to effect a change over from war work to peace time productions, is easily the most exciting period known in the history of the motor industry. Happily the outlook is of the rosiest kind. Apart from those keen riders who have tested the joys of the open road and long to renew

their pleasures a wheel, there is the vast army of converts, who, having earned fame and glory Overseas, and with a little bank balance to their credit, are ready to speculate in the most economical form of motor vehicle extant. Whatever their opinion of the reliability and usefulness of a motor cycle before going Overseas, no doubt on those scores now exists, for, under their very eyes, day in, day out, they have witnessed the ability of a motor cycle ready to go anywhere and to do anything. Our despatch riders—all credit to them—have proved missionaries in disguise. Unfortunately, cheap motor cycles are not to be—yet awhile.

Manufacturers can be relied upon to profit by their war-time experience of quantity production methods. Those lessons mean standardisation and standardisation spells low production costs, and, of course, low selling price. Design? Well, we are not all going to be satisfied with one and the same kind of machine. The more varied the selection the more interesting one's riding experience. Two strokes? Ah! their sphere is apparently still to be limited to the lightweight bicycles. In that field they will remain pre-eminent, for a two-stroke is the simplest form of bicycle motor, and the easiest to produce. A return to the 500 c.c. single would not surprise me. What better service could an engine render than the 500 c.c. singles of six years ago?

V twins? Well, the popular fallacy that a twin-cylinder engine requires double the amount of attention that a single demands is surely finally dispelled. Properly designed, with more efficient lubrication systems, and the selection of metals scientifically studied, twins (type no matter) will be the rule in the peace that is coming. But—and it is a big but—we do henceforth expect silent and durable valve gear. It is not nice to instance importations in talking of desirable improvements, but American—and Swiss—twin-cylinder engines must take the palm for the silence of their valve operating mechanism. That state of affairs should not be allowed to continue.

Aero engine experience may not be reflected in early designs so much as its effects will be apparent at Olympia, 1919. But it is in the T.T. races that all those discoveries and developments that have attained for Britain the supremacy of the air will be exploited. Unfortunately, questions of cost stand in the way, or we might see more aluminium jacketed cylinders, or steel cylinders with copper depositing on standard touring machines. Carbon still forms much too readily on most types of air-cooled engines, and leads to the objectionable habit of knocking. Correct piston design can mitigate this failing. Of the more general aspects, however, we do expect—nay, demand, to see perfect interchangeability of parts

Capt. G. Smith

when replacements become necessary, rust-proof finishes wherever possible, better design and material for valves (breakages of which should be unknown after aero engine experience), better weatherproofing, improved accessibility of parts that matter, sales and distribution methods improved, and a continued interest in a machine after it has left the factory.

From Mr. W. H. Wells, of the Hendee Manufacturing Co.

HAVING been identified with motor cycles since their very inception, I have come to the conclusion that motor cycles, in the future, will eventually resolve into two types only.

Passenger Machines.—The first and most popular type will be a high-power three-speed gear sidecar machine. This model must be designed by the makers solely with the idea of its being a passenger-carrying vehicle. The frame and forks must be constructed so as to withstand the severest amount of side strain to which a sidecar subjects them. The rider's comfort should be studied in the matter of large tyres, ample mudguards, and a reliable electric lighting system. Very few who have ever driven a sidecar combination would care to go back to the solo mount; and this applies particularly to those fairly well advanced in years.

Solo Machines.—There will always be a demand for a solo machine amongst the young and more sporty class of riders; and this machine should be so designed that it can be easily handled, light in weight, and low to medium in power. The rider's comfort need not be studied to such a great extent as with the passenger machine, particularly as gadgets add weight, which is undesirable for the solo rider. I would not recommend dynamo and battery electric lighting for the solo machine; it all adds weight, which is undesirable, and tends to make the solo machine unwieldy. I should be glad, however, to see a light, practical friction-driven generator, which would weigh less than a gas-lighting outfit, perfected for motor cycle use. A few crude types, but fairly efficient, were produced just before the war started.

Many manufacturers are too inclined to listen to more or less unpractical ideas emanating from the riding public, with the result that they find themselves loaded up with so many models that economical manufacturing becomes almost an impossibility. I think the time has now arrived when the older established manufacturers have gained enough experience to know what the public want and what is suitable for them; and by eliminating all superfluous models, and getting down to a sound, economical manufacturing basis, they can give the public better value than when they manufacture a multiplicity of models.

Mr. W. H. Wells

DELLA FERRERA MOTOR CYCLES.

Italian War Office Models to be made for the Public.

ONE of the several Italian makes of motor cycles which has been used extensively by the Italian Army during the war is the Della Ferrera, of which photographs showing two models are reproduced here. We are informed by our Milan correspondent that these machines will be made for the public this year, and that the Italian motor cycle trade—a rapidly growing industry—will make a great effort to capture the greater part of their home trade. This fact, coupled with the probable early arrival in Italy of the new American models, will make it increasingly difficult for the British manufacturer to pick up his pre-war trade,

which was very flourishing. Several new firms have announced their intention of entering the motor cycle trade and many interesting new machines, including at least two flat twins and a two-stroke, are on the tapis.

Specification.

We have from time to time illustrated many of the Italian machines, which, it may be remembered, very closely follow British lines. The Della Ferrera is no exception to this rule.

The single-cylinder Della Ferrera has a bore and stroke of 90 and 100 mm. respectively while the cylinders of the twin

are 80 x 100 mm. bore and stroke. The capacity of the former is 636 c.c. and 1,006 c.c. in case of the latter.

In all other respects the specifications of the two models are identical and include Dixie magneto, countershaft gear, four speeds, dry plate clutch, kick-starter, and internal expanding rear brake.

The gear ratios are 4, 6, 9, and 13 to 1, obtained by two pairs of chains (two from the engine to the gear box and two to the rear wheel). These are completely enclosed. The kick-starter operates directly upon the engine shaft, while in the rear wheel sprockets is embodied a shock absorber of the rubber cushion type.

The Italian Della Ferrera twin of 1,006 c.c. and single of 636 c.c.

A PRESSED STEEL FRAME.

FROM time to time we have recorded the efforts of designers and would-be designers to produce a motor cycle frame of pressed steel. So far, however, the results have not been so encouraging as the possibilities of the proposition seem to offer.

Mr. F. W. Barnes, whose name is familiar to all who follow the sport and pastime, seems to have gone beyond the "idea" stage, and has succeeded in designing a frame on these lines, which, while being entirely unorthodox so far as method of construction is concerned, is by no means unsightly.

The main or body portion of the frame is formed of two metal stampings welded on their adjacent edges. This portion is shaped at the front and rear ends to provide seatings for the two diagonal members of the frame, at the lower end of which the engine is intended to be fixed. The fore bracket is formed of a metal plate bent to form the steering

head. The rear bracket is bent around the rear end of the tank or body portion in a similar way. The front fork, too, is intended to be of pressed steel construction, while the rear stays may follow the same principles.

BOWSER SIDECARS.

MESSRS. E. BOWSER, sidecar manufacturers, 50, Park Lane, Leeds, inform us that they have only just concluded their Government contracts, and are now engaged upon making the types of sidecars which they manufactured prior to the war. Their principal production will be the original Bowser two-seated sidecar, and they are hoping in the course of a few months to be able to place on the market some new designs of two-seated and single-seated sidecars which will mark distinct progress in sidecar production.

THE CHEVROLET PISTON.

AN effort to overcome piston slap and wear of pistons and cylinder walls has been made the subject of a recent patent.

The difficulty which the invention sets out to overcome is that due to the loose fit of the ordinary piston in the cylinder when cold, so that there is a tendency for the piston to "slap" on the sides of the cylinder wall at the points at right angles to the axis of the gudgeon pin until warmed up and expanded to a good fit. The inventor's method is to make the skirt of the piston slightly oval, the largest diameter to be a good working fit

in the cylinder when cold. The upper part of the piston carrying the rings is turned rather smaller than the lesser diameter of the skirt, so is always quite free. The difference between the radii of the major and minor axes of the piston skirt is said to be quite satisfactory at .002 in.

It will be seen, that there is a permanent area of contact between the piston and the cylinder walls, and the expansion takes effect in a line with the gudgeon pin. Also the action when running cold is to distort the piston by the pressure between the gudgeon and the cylinder wall so as to increase the bearing area with the increasing pressures.

The Chevrolet piston, designed with the idea of preventing piston slap and wear on the cylinder walls.

A patented design for a pressed steel motor cycle frame.

A Two-stroke "Runabout" of Thirty Years Ago.

Some Particulars of the Butler Motor Tricycle made in 1888, which is claimed to be the First Petrol Vehicle in this Country.

IT is not generally known that a little petrol-driven tricycle was built in this country in the year 1888, and that the engine was of the two-stroke type. This was the Butler petrol cycle, of which the first design was exhibited at the Inventions Exhibition in 1885, while the provisional patent is dated 1884—thirty-four years ago.

Truly one may say that this was the first cycle car, and it is remarkable that it had electric ignition, clutch control, an epicyclic gear, and stub axle steering such as is common practice on cars to-day.

A study of Mr. Butler's pioneer machine is most interesting, and the mechanism needs very careful investigation if all its ingenuity is to be appreciated.

The method of working out the two-stroke principle is different from conventional practice to-day. From a pressure diagram before us, it is clear that a more perfect exhaust stroke is obtained than even in a four-stroke engine, while the charge is only transferred after the piston has reached the top of the stroke. The main advantages are perfect exhaust and perfect charge, so far as the working cylinder is concerned. The disadvantage of this principle would be an unduly high receiver pressure needed for the transfer.

In all it appears to be a system which, if taken up again and modernised, might give good results, particularly as regards the thermal efficiency.

The *Automobile Engineer* of March, 1916, gave the following description as provided by the inventor:

"There are two cylinders, one at each side of the driving wheel, and arranged acting away from the driving cranks, in order to work with an unusually long stroke and to have the front ends arranged as compressing pumps. The pistons are connected by rods to cross-heads, and these by return connecting rods of oval section tapered steel tubes to the cranks, which are at 180°. Each cylinder is self-contained, and draws in and compresses mixture at the front end into a pressure chamber arranged underneath, a jacket surrounding the pressure chamber being utilised to heat the mixture. The cylinders are 2½ in. diameter by 8 in. stroke, and the mixture, com-

pressed to from 15 lb. to 30 lb. per square inch, according to throttle opening, is admitted to the explosion end of the cylinders for 2½ in. of the power stroke, when it is cut off by the rotary valve and immediately ignited by a wipe contact spark, produced

by a spring point extending some 3 in. from a plug screwed into the cylinder cover." A pressure diagram, which appeared in our sister journal *The Automobile Engineer*, was produced when the motor was running at about 300 r.p.m. and with the throttle fully open. From this it was seen that the pressure was between 20 lb. and 30 lb. for the first 2 in. to 3 in. of the stroke, rising to 100-120 lb.

after the crank had moved to about 60° of the power stroke.

The Method of Starting.

"At each end of the cylinders there is a balanced tapered rotary valve driven at half speed by a sprocket wheel and chain. Between the rotary valves and the pressure chamber there are two plug throttles, and a third plug to control the admission of mixture from the carburetter to the compressing end of each cylinder. The purpose of the three plugs is to enable the motor to be used as a compressor while pushing it along the road for a hundred yards or so to charge up the cylinders, after which operation the plugs are moved round a few degrees to start the motor under air pressure with the driving wheel raised off the ground. Immediately on the chambers commencing to fire, the plugs are moved round to the third position to place the compressing ends into connection with the pressure chambers.

"In practice it was found that the motor would not work slowly enough to propel the car along unaided at the start, i.e., when the driving wheel was lowered to the ground, and the car had to be pushed along at a running speed until both cylinders picked up.

The motor, however, would run very satisfactorily with the driving wheel running on a pair of grooved pulleys when allowed to speed up to about 250-300 r.p.m.

"The current for the ignition was at first obtained from a dynamo magneto, but as this took up so much of the available power a primary battery was

Side view of the "Petrol Cycle," showing its curious construction.

A pioneer designer and his three-wheeled runabout of 1888.

MOTOR CYCLES

Manufacture Resumed

Orders for Ariel Motor Cycles are now being accepted for home and export delivery.

Being gradually released from our Government contracts we hope to give early delivery of Ariel $3\frac{1}{2}$ h.p. single-cylinder models.

The Ariel Catalogue may be had upon enquiry.

A Two-stroke Runabout of Thirty Years Ago.—

substituted. At first a Bunsen nitric acid battery was used, then a bichromate of potash, and finally a silver-carbon plate battery known as the Shancheef, really a modification of the silver-copper Smee battery. The carburetter was placed forward, just over the petrol tank, and was within reach from the seat for adjustment of the petrol feed by a pin valve; this carburetter had a jet feed and automatic air plug to maintain a constant mixture for different positions of the throttle and for varying speeds. In the trials Pratt's gasoline was used, although the motor would run on commercial benzolene, but did not start so quickly on the heavier spirit.

"After a considerable amount of experimental research with the motor arranged to work on a pressure admission two-stroke cycle this was decided to be unsatisfactory, and the motor was altered to work four-stroke, when the pressure chambers and the valves at the compressing end of the cylinders were cut out, and the valve at the explosion end altered to admit mixture at alternate forward strokes instead of at each stroke as formerly. An epicyclic transmission gear was also fitted in the hub of a new driving wheel, which now allowed

the motor to speed up to 400-500 r.p.m. when running along the road at from eight to ten miles an hour. The four-stroke motor ran much better, and after being first started by a handle on one of the cranks, with the driving wheel raised from contact with the ground, the car could be quite easily started from the seat by a foot lever at the right-hand side of the footboard. This method, although seemingly strange, really worked very well, as the driving wheel

could be let down quite gently with the toggle lever control. On the left side of the footboard was a second foot lever for the brakes on the front steering wheels. These were carried by stub axles swivelling in sockets, and were connected for the three wheels to focus to one point when steering in either direction. The cylinders were jacketed and connected by large pipes to a water tank arranged over the driving wheel, which,

although heavy, appeared to keep the cylinders from overheating. This little car, although of short wheel-base, and with wheels only 32in. and 30in. in diameter, weighed with oil and water 400 lb. After being altered from two-stroke to four-stroke, the ignition was changed from wipe spark low-tension to high-tension, with a sparking coil and rotary distributor."

Details of the two-stroke Butler engine, which embodied electric ignition and jet carburetter.

THE UNIT SYSTEM.

The Integral Engine—Gear Box and Belt Drive.

IN any design of any machine there appear to be three periods.

- (1.) The simple idea developed on crude lines.
- (2.) The fitting of various devices which experience demands as essential, but which are frequently added in a disconnected sort of way.
- (3.) The "clean sweep" of the existing details, a unification of all the essential features, and the embodiment of them in such a way as to make a design thoroughly sound.

The motor cycle at present appears to be in stage 2, particularly in regard to the transmission problem, on which depends perhaps the success of the machine. The need of the change-speed gear has given rise to a remarkably diverse development, but there has been no genuine attempt to establish a modern unit system applicable to all sizes of machines.

The all-positive system is *not* the ideal for the motor cycle, however I may be held up to ridicule by the comparison of car progress; I maintain that in a motor cycle we have an entirely different set of conditions—we have a comparatively flexible frame, and no one will contradict the opinion surely that the present positive systems of drive have to be made needlessly heavy so as to allow for errors of alignment due to the interposition of a section of this relatively flexible frame.

The unit system is a step to secure the true alignment of gears, under all conditions, of the change speed gear system. It will be agreed that the best has never been got out of the simple yet much maligned belt drive, simply because it has been put to work under conditions which in themselves damned the belt drive—the use of too big a belt reduction ratio. I want to suggest that, if the unit system be adopted, the change speed gears are placed in front of the engine and the advantage taken to give 6in. or 8in. more to the centres of the belt drive. The use of a big reduction between engine and belt pulley would allow of a large diameter pulley on the counter-shaft, and would give the belt system a new life.

The combination of the unit system with a properly designed belt drive would result in a much lighter machine per h.p., especially in the larger machines, and this is a very desirable aim to keep in view. So great a percentage of the engine h.p. in modern day practice is spent in propelling a heavy machine.

No doubt there are many who would like this problem thoroughly ventilated, and I hope manufacturers will concentrate on the unit system, with its ease and centralisation of production and its unquestioned assured reliability. In other words, we want an engineering prophet to arise who will make the clean sweep.

W. SYMES.

THE BUYERS' GUIDE.

Current Prices and Delivery Dates for 1919 Motor Cycles.

CONSIDERING that it is scarcely two months since the Armistice was signed, the trade has made remarkable progress towards re-establishing itself as a motor cycle industry. From the following schedule, it will be seen that quite a large number of makes will be available shortly. The majority of the prices given are subject to alterations as time reveals to the makers the actual cost of production. In the meantime, the rise in prices above the pre-war level is not so high as the extra cost of every other commodity from matches to wearing apparel.

No doubt the comparatively high prices of new machines will temporarily enhance the value of the second-hand motor cycle.

It is interesting to note that the Morgan Runabout and G.N. cycle car are quoted at prices competing with the de luxe sidecar combination, while the average price of 3½ h.p. three-speed machines is in the neighbourhood of £80, and the two-stroke two-speed is about £50.

The 3½ h.p. sidecar is now over £100, while 6 h.p. and 8 h.p. models range from £125 to £152. So far, the A.J.S. has the distinction of being the highest-priced motor cycle, while the Norton "big 4" leads the singles.

Space does not allow a detail review of these prices and delivery dates, but in subsequent issues we hope again to refer to these matters, which, at the present time, are of great interest to motor cyclists and potential buyers.

THE 2¾ h.p. COULSON.

An Entirely New Product of Medium Power and Weight.

A NEW motor bicycle which will shortly be placed on the market is the 2¾ h.p. Coulson. This will be a mediumweight machine of medium horse-power, and one capable of going anywhere. It has been generally found that a horse-power of 2¾ is the most practical power the motorcyclist can desire. It will not give him excessive speed, but will enable a good average to be kept up and any hill to be climbed.

The engine fitted is a 2¾ h.p. Blackburne, 71 mm. x 78 mm., 341 c.c., which is referred to in the Burney and Blackburne programme appearing in last week's issue. This engine has the same size crank case and the same size valve as the 3½ h.p. The frame will be constructed of 1½ in. light gauge tubes, combined belt and chain transmission will be fitted, while the gear box will be a two-speed Jardine. So far as

suspension is concerned, the rear portion of the machine will be provided with leaf springing, while the front of the machine is suspended on Druid Mark II. forks.

It will be noticed that the mudguards are provided with valances of ample size, and that the top tube of the frame is of the sloping variety, and that the machine has a distinctly racy appearance. A Best and Lloyd drip feed lubricator is fitted and a Brooks saddle, the ground clearance being 4½ in.

The machine is being brought out by Mr. F. A. Coulson, formerly managing director of the Wooler Engineering Co., and it is expected that between 750 and 1,000 machines will be made during 1919. Already, half this number is booked up.

Further particulars can be obtained from the F. A. Coulson Manufacturing Co., 199, Piccadilly, London, W.1.

The new Coulson lightweight model. It is fitted with 2¾ h.p. Blackburne engine.

NEW THOUGHTS.

READERS' OPINIONS ON MATTERS OF THE MOMENT.

A Russian aviator discusses the ideal machine for Russia, and describes a "constant speed" device.
A British naval lieutenant makes a plea for better garages. The disposal of Army motor cycles.

Russia's Needs.

LT. NICOLAS OLECHNOVICH, a Russian engineer and air pilot, writes to us on the requirements of the Russian market. He is at present in England, but so soon as order is restored he intends to open a motor cycle agency in Russia. Just before the war (he writes) the Russian market was fully covered by American machines, and the sale of British machines was very limited. The causes of this were (1) the conditions of the English credit system, and (2) the machines were too expensive.

In those days the only type of English machine to be seen in Russia was the lightweight, and, according to our correspondent, this kind of machine is not strong enough for Russian roads. The lieutenant also refers to the fact that the agents for British machines do not stock spare parts. If replacements were required, there has been a delay of a month or more waiting for the part to come out from England. Owing to this delay, most riders preferred to patronise the local ironworks or make the parts themselves. As a result of these drawbacks of the British machine and the handling of it as a commercial proposition, the American machines have found a larger market, because they are much cheaper, they have large engines, large tyres, and "spare parts in plenty."

A Constant Speed Device for the dynamo has been patented by Lt. Dyamo Drive. Olechnovich. According to the inventor, this invention automatically provides approximately a set speed for the dynamo irrespective of the speed of the machine. In practice, we are advised, the speed of the dynamo is approximately constant throughout the machine's range of speed from 4 to 60 m.p.h.

From the diagrammatic drawing it will be seen that the device consists of a box containing two discs, the shafts of which are parallel. Between these two discs is a friction wheel carried on a hollow shaft, which slides upon a stationary spindle. Fixed to the friction wheel sleeve is a governor of the conventional centrifugal type, by which the friction wheel is made to rise and fall according to the speed at which it revolves, and consequently alters the speed ratio between the driving and the driven discs.

A constant speed device for dynamo drive. (A.) Driving pulley. (B.) Driving disc. (C.) Intermediate friction wheel. (D.) Driven disc. (E.) Universal joint. (F.) Dynamo. (G.) Centrifugal governor

vide a machine of the following specification: Spring frame, 28x3in. tyres, high position of engine, which should be over 1,000 c.c. capacity, large tanks, and dynamo lighting set.

Overseas Finish.

LT. OLECHNOVICH is of the opinion that for Overseas machines a superior exterior finish is not necessary for every part. The Russian buyer looks only for good material, best workmanship, and, as far as possible, rustless finish. When two metals in contact are wet, a galvanic couple is set up. It is a mistake to have a layer of copper deposited on steel for nickel-plating, because the copper is a positive and the steel a negative. It is necessary to have a negative finish, such as zinc. The lieutenant thinks that future demands for motor cycles in Russia are very great, and in order to secure a share of this market British makers should provide a machine of the following specification: Spring frame, 28x3in. tyres, high position of engine, which should be over 1,000 c.c. capacity, large tanks, and dynamo lighting set.

Garages.

"G.P.G.K.," a naval lieutenant, writes on a question which should be considered more seriously than hitherto. He urges motor cyclists to "make the small garage proprietor put more method into his concern," but does not suggest how this can be done. It would appear that, in the first place, it is a matter for the R.A.C. and A.C.U. to take up, and to appoint only "men with method" as their official repairers. "G.P.G.K." writes as follows:

"Every motor cyclist knows the small garage troubles in pre-war days. Chiefly, the toolbag thief, small part thief, lack of accessories sold by the proprietor, office and store muddled together with completely drastic results, and many other minor worries.

"Now the motor cycle renaissance is coming let us make the small garage proprietor put more method into his concern.

"Official repairing signs of well-known clubs were displayed at garages which were no more than a shed for storage purposes. Let us improve pre-war motor cycling conditions."

Army Motor Cycles.

ANOTHER interesting letter is from Mr. C. S. Moores, of Bristol, who suggests that men who have served in the Army should have preference in buying war-worn machines.

The disposal of W.D. machines is a great problem, and, in all probability, a great deal of dissatisfaction will be expressed on the manner in which this matter is being handled by the Government. Mr. Moores's letter is given below:

"It was recently suggested in *The Motor Cycle* 'that men who have been riding machines should have the option of purchasing them.' This is quite in order as far as mobile units are concerned, but what about the motor cyclist who has served in the Infantry? Is not he entitled to purchase an Army motor cycle at a low price? I think the following points are worthy of consideration:

"(1.) That the sale of military motor transport be restricted to men who have served in the Forces.

"(2.) That machines be sold by auction to the highest bidder.

"(3.) That any soldier on discharge may have the option of obtaining a permit entitling him to purchase one motor cycle, car, or lorry.

"(4.) On purchasing a machine this permit to be handed to the vendors.

"Commenting on (1). This obviates the chance of big firms buying up large stocks and making 'second' profits. (2.) Enables the Government to realise a fair price for the machines the State has paid for. (3.) Men who have served in the Army are certainly entitled to any advantages the Army may offer, in preference to civilians. (4.) Ensures that every soldier is treated with equal fairness, and avoids one person being able to buy in quantity."

An Anglo-Canadian Proposition.

THE fact that the Canadian market has not been exploited by British motor cycle manufacturers is a point often discussed by Canadian riders, so many of whom have now had an opportunity of seeing the English product. We give below a short letter from a Montrealer at present in this country.

"British manufacturers," he writes, "will never realise the enormous possibilities of the Canadian market until they visit the Dominion. I feel sure that if they could but appreciate this they would make an effort to secure their full share by building machines suitable for our country and our pocket. To do this they must be made over here. Isn't there a British firm with sufficient enterprise to start a Canadian factory, or perhaps it would reduce the cost of production if the parts were made in the Home factory and assembled in Canada."

CURRENT CHAT

Times to Light Lamps.

GREENWICH TIME.

"	11th	...	4.42 "
"	13th	...	4.44 "
"	15th	...	4.47 "

Death of a Well-known Motoring Pioneer.

We regret to learn that Mr. Noel B. Kenealy has died at Nairobi, British East Africa, where he was editing a local paper. He was editor of *Motoring Illustrated* and the founder of the Herts Automobile Club.

Secretary of Road Board Resigns.

We learn that Mr. W. Rees Jeffreys has resigned his position as secretary of the Road Board, and accepted the position of financial adviser to the Motor Union Insurance Co., Ltd., of which he was one of the founders.

More Petrol for Motorists.

Though the restrictions on the use of motor vehicles have been removed, it is not yet possible for the Petrol Control Department to dispense with the system of licences to obtain motor spirit. Under the Finance Act, 1916, a duty is payable by holders, and until the Act is repealed by Parliament licences will continue to be necessary. New applicants have no difficulty in obtaining licences. The quantities of spirit that the Department is prepared to allocate to existing licence-holders are now very much greater, and no reasonable requests will be refused. The Motor Spirit Restriction Orders will be revoked entirely by the Board of Trade from January 10th.

Petrol Allowances.

We are informed by the Petrol Controller's Department that the following allowances will be made to motor cyclists: Six gallons per month to owners of solo machines; ten gallons a month to owners of sidecar machines, and in exceptional cases, where the machine is in the employ of a recognised firm, an allowance up to fifteen or sixteen gallons a month. Tricars, by which we presume that trade carriers and Morgans are meant, will be allowed sixteen gallons a month.

Accessory Thieves' New Tricks.

We quote from a letter received from a reader: "A few weeks ago I inserted an advertisement in *The Motor Cycle* for a Williamson for sale. While away from home a prospective buyer called, and asked to see it. My wife showed him the machine, and left him for a few minutes. When she came back from the house he expressed every satisfaction, and left, saying he would buy it, and that he would call to see me later. When I returned I missed one set of J.A.P. and two King Dick engine spanners, which could only have been taken while he was left alone, as the shed where the machine was kept was previously locked. Needless to say he did not turn up as arranged."

Special Features.

THE FUTURE OF SURPLUS GOVERNMENT MACHINES.
SINGLE, TWIN, OR FOUR.

Bluemel Brothers, Ltd.

At the annual meeting of the above, the directors recommended the payment of a dividend on the ordinary shares of 1s. 4d. per share, less income tax, amounting, with the interim dividend paid in June last, to a total of 10%, plus a bonus of 1s. per share, less income tax, making 15% for the year.

A Motor Cycle Club for Ealing and District.

It is proposed to form a motor cycling club for Ealing and District. It is the intention of the promoters to maintain a vigorous and novel programme, including an entirely new form of inter-club team competition, which, it is hoped, will greatly stimulate club activity. The social side will be well catered for, the club having had the offer of the use of a large club room gratis. In this connection, club runs will be eagerly looked forward to after the enforced idleness of the past four years. These runs will be combined with a social event, and will give members an object in riding. Lady riders are invited to join, for it is felt that the lady members will be well represented by ex-R.A.F. motor cyclists and others. The club will be affiliated to the Auto Cycle Union, whereby members will become entitled to the privileges conferred by that body. The cycle car user's interests will be studied, and a class arranged for this vehicle in competitive events.

Every rider who is interested should write to Mr. S. P. L. Brown, 25, Orniston Road, Shepherd's Bush, W.12

A meet of motor cyclists on a recent Sunday at Owl Bar. This rendezvous was a popular one for Sheffield riders before the war.

Honour for Well-known Motor Cyclist.

Mr. Guy Lee-Evans, one time famous Indian rider, has been awarded the O.B.E.

Belgian Motor Cycle Trade.

Belgian manufacturers of cycles and motor cycles are about to form a society for their protection and to further the manufacture and export of Belgian machines.

Lecture in Sheffield.

On January 18th, Mr. L. B. Henderson, A.M.I.A.E., will speak on the care, upkeep, and tuning of motor cycles before the Sheffield District N.M.C.F.U. The lecture will be held in the Imperial Hall, Pinstone Street, Sheffield.

The Industrial Reconstruction Council.

A conference on "Reconstruction or Restoration" will be held under the auspices of the Industrial Reconstruction Council on Tuesday, January 14th, at 6 p.m., in the Hall of the Institute of Journalists, 2 and 4, Tudor Street, E.C.4. The chair will be taken by Sir Henry Urwick, of Messrs. Fownes Bros. and Co.

The War Work of the M.A.G. Engine Designer.

Mr. Osborne de Lissa, of the M.A.G. Engine Co., Ltd., whose "Opinion" we give on another page, was, during the war, appointed to a position in the M.O.M. Gun Machine Tool Department, and later transferred to the Technical Department of the Air Ministry.

A Stolen Motor Cycle.

A reader of *The Motor Cycle* who is quite well known in the competition world has recently had his motor cycle stolen by means of an ingenious trick. Immediately after he had left his residence a soldier called upon his wife, saying that he had called at the request of the owner on behalf of a certain major to take delivery of the machine, which was advertised for sale. It has not been seen since.

The motor cycle is an Imperi two-stroke, all black finish, tank enamelled French grey and green, complete with horn, lamp, new tyres, and belt. The magneto chain cover is broken near the top, and the off-side footrest has been broken and not very neatly welded. Should anyone hear of this machine he is requested to correspond with the Editor, *The Motor Cycle*.

Second-hand Prices.

We give below the average prices of motor cycles and combinations from advertisements which have appeared in three previous issues of *The Motor Cycle*:

	1913 and Earlier.	1914. '15-'16.	'17-18
A.J.S., sidecar	£75	£85	—
Allon, 2-stroke, 2-speed ..	£26	£35	£38
Alldays, 2-stroke, 2-speed ..	£25	—	—
Ariel, 5-6 h.p., sidecar ..	£65	—	—
Bat-Jap, 8 h.p., sidecar ..	—	£70	—
Bradbury 4 h.p., belt ..	£20	—	—
Calthorpe, 2-stroke	—	£27½	—
Calthorpe-Jap, 2½ h.p., 2-s.	—	£28	—
Ditto, 6 h.p., sidecar ..	—	£70	—
Chater-Lea, sidecar	£39	£50	—
Clyno	£63	£58	£100
Douglas, 2½ h.p.	—	£36	£40
Douglas, 4 h.p., sidecar ..	—	£60	—
Enfield, 6 h.p., sidecar ..	—	£50	£85
Harley-Davidson, s/car.	—	—	£80
Hobart, 2-stroke	—	—	£35
Humber, 3½ h.p., 2-speed ..	£20	—	—
Indian, 7-9 h.p., sidecar ..	—	£47	£56
James, 3½ h.p., sidecar ..	—	—	£90
Levis	—	£24	—
Matchless, 6 h.p., sidecar	£60	—	—
New Hudson, 3½ h.p., s/c.	£32	£40	—
O.K., 2½ h.p., 2-speed ..	—	—	£30
Premier, 3½ h.p.	£22	—	£33
Rover, 3½ h.p.	—	—	£66
Rudge-Multi	£19	£31	£57
Sunbeam, 3½ h.p., s-car.	—	—	£70
Triumph	£25	£38	£49
Zenith, 8 h.p.	—	—	£65

Where the A.B.C. is to be made—the Sopwith aviation factory at Ham, Surrey. The A.B.C. programme consists of the production of a spring frame four-speed 3 h.p. flat twin lightweight, which is to sell at £70.

PROHIBITION ON EXPORTS REMOVED.

IN a recent issue, when writing of the coming motor show at Barcelona, we referred to the difficulty experienced by British makers in getting the necessary permits to export their goods. In view of the urgency of the matter we also wrote to the Board of Trade on the subject, and are pleased to be able to tell our readers that the difficulties to which we alluded are now entirely removed. We append our letter to the President of the Board of Trade, together with the reply which we have received:

The President of the Board of Trade.

Dear Sir,—I have received information from Spain that a motor car and motor cycle exhibition is to be held in Barcelona early in March next. My correspondent informs me that, while American manu-

facturers are sending to this exhibition everything that is asked, British makers, although in many cases they have the goods in stock, are finding difficulty in obtaining the necessary permits to enable them to export the goods before it is too late.

May I therefore, with all due respect, lay before you the extreme importance of this matter, in view of the very serious position in which the motor cycle industry of this country finds itself in its present competition with its chief rival, and urge the desirability of immediately removing the restrictions which have, as a necessary war measure, been placed on the export of manufactured goods.

Your obedient servant,

THE EDITOR.

Board of Trade (Commercial Relations and Treaties Dept.), Whitehall, S.W.1.

Sir,—With reference to your letter of December 27th, I am directed to draw your attention to the notices which have appeared on pages 791 and 819 of the *Board of Trade Journal* of December 19th and 26th respectively, from which it will be observed that the goods in question have been transferred to List C of prohibited exports. I am at the same time to point out that by an Order of Council dated December 24th, 1918, Spain was added to the countries excepted from the prohibitions relating to articles included in that list, and that goods referred to can therefore be exported to Spain without licence.

Your obedient servant,

H. FOUNTAIN.

"SINGLE," "TWIN," OR "FOUR?"

The Lessons of the Plebiscite. Data concerning the Proportionate Popularity of Various Types of Engines.

IN announcing the result of the "Which Type" referendum last week, we stated that, although the flat twin as a solo machine engine secured the greatest number of readers' votes, the single-cylinder was a very close second.

We repeat this in justice to the single-cylinder engine, and in full appreciation of the probability that, whereas this type of engine secured its support on good service in the past, the flat twin scored more on its *theoretical* advantages. This is not saying that practical experience with a flat twin would modify this judgment, but we think quite a large percentage of those readers who regard the 500 c.c. flat twin as their ideal have based their preference on theory, because it is doubtful whether, excepting the $2\frac{3}{4}$ h.p. Douglas, so many flat twins have been produced as the number of forms specifying it which have been received.

The various types were represented by the following percentages:

	Solo.		Sidecar.
Flat twins	40%	28%
Singles	36%	16%
V twins	13%	35%
Four-cylinder	5%	20%
Other types	6%	1%
	100%		100%

Two-stroke or Four-stroke.

Considering the number of "utility" two-strokes on the road, and the evidence that they are giving their owners satisfaction, it is, at first sight, rather surprising that their popularity was not registered. The voting on two and four-strokes was as below:

	Solo.		Sidecar.
Two-stroke	6%	4%
Four-stroke	94%	96%

Before concluding that the two-stroke has really lost its popularity, and that the above figures are a true indication regarding the demand in the future, it is well to view the matter in its broadest aspects.

The main object of the Referendum is to assist manufacturers to judge public opinion, therefore it must not be overlooked by them that the majority of users of the little two-stroke buy it because it

is cheaper than a four-stroke, and that if such riders have ideals, in all probability these would include larger and more powerful engines than the usual two-stroke, of such a size of cylinder, in fact, as does not exist in two-stroke engines. Again, the two-stroke machine is used more as a utility machine than as a sportsman's mount, and to the former class of rider mechanical ideals do not exist. He requires a machine for general "pottering about," and so long as the little two-stroke does this, he does not trouble.

Therefore, the fact that so few of the total forms specify two-stroke engines is no criterion that no demand exists for the simpler type. It appeals to a totally different class of rider from that which responded to our invitation to compile a specification.

Incidentally, it should be noted that the number of engines under 300 c.c. which were specified was infinitesimal: in fact, solo engines of over 1,000 c.c. scored over ten times the votes. The two-strokes mentioned were of suggested new types.

Engine sizes were divided up as follow:

SOLO ENGINES.

Under 300 c.c.	0.04%	700 c.c.	3.7%
300 c.c.	3.8%	750 c.c.	4.7%
350 c.c.	5.0%	800 c.c.	1.5%
400-475 c.c.	1.5%	850 c.c.	0.3%
500 c.c.	32.7%	900-925 c.c.	1.2%
550 c.c.	21.5%	975 c.c.	1.3%
600 c.c.	9.8%	1,000 c.c.	5.0%
650 c.c.	5.8%	1,050 c.c.	0.5%
675 c.c.	1.0%	1,100 c.c.	0.7%

SIDECAR ENGINES.

500 c.c.	4.9%	850 c.c.	2.2%
550 c.c.	6.8%	900 c.c.	5.5%
600 c.c.	7.2%	925-975 c.c.	5.4%
650 c.c.	5.0%	1,000 c.c.	31.0%
700 c.c.	4.9%	1,050-1,100 c.c.	1.4%
750 c.c.	19.8%	1,200-1,500 c.c.	0.9%
800 c.c.	5.0%		

If we divide the engines of the solo class into groups we see that solo riders are more enthusiastic concerning higher powers than 500 c.c. than for engines smaller than this size:

Under 500 c.c.	10.3%
500-600 c.c.	70.8%
700 and over	18.9%

The popularity of the above three types, according to the voting, is in the following order: Flat twin, single, and V type twin.

Single, Twin, or Four?—

Dividing up the sidecar engines in a similar way, we obtain the following figures:

Under 650 c.c.	23.9%
700-900 c.c.	37.4%
Over 900 c.c.	38.7%

* Including 31% 1,000 c.c..

From the above it will be seen that over 75% favour engines larger than 700 c.c. for sidecar work, and that a proportion greater than this prefers engines of 500 c.c. and over for solo use. Before the war the trend of design was towards the 750 c.c. twin for sidecar work and an engine smaller than 500 c.c. for solo purposes. What has happened to cause this ebb and flow of public opinion? Is it the usual cry of the enthusiast for more and more power? Certain it is the 350 c.c. engine just fails fully to satisfy the solo rider who requires speed and means to maintain high averages. The 500 c.c. engine gives him that extra reserve which in the sidecar class is represented by the difference between 750 and 1,000 c.c.

So far, we have considered figures broadly. In order to gauge public opinion correctly, it is necessary now to take each type of engine separately. We then find the proportionate popularity of the various sizes in the different types.

ENGINES FOR SOLO MACHINES

Single-cylinders.

300 c.c.	6%	550 c.c.	30%
350 c.c.	7%	600 c.c.	10%
400 c.c.	1%	700 c.c.	2%
500 c.c.	44%		

Flat Twins.

300 c.c.	3%	600 c.c.	12%
350 c.c.	8%	650 c.c.	5%
400 c.c.	1%	700 c.c.	4%
500 c.c.	52%	800-1,000 c.c.	1%
550 c.c.	13%		

V TWINS.

400-450 c.c. ...	2%	700 c.c.	4%
500 c.c.	18%	750 c.c.	22%
550 c.c.	10%	800 c.c.	2%
600 c.c.	8%	850 c.c.	2%
650 c.c.	8%	1,000 c.c.	24%

FOUR-CYLINDER.

600-650 c.c. ...	20%	1,000 c.c.	35%
750 c.c.	15%	1,100 c.c.	14%
800-900 c.c. ...	16%		

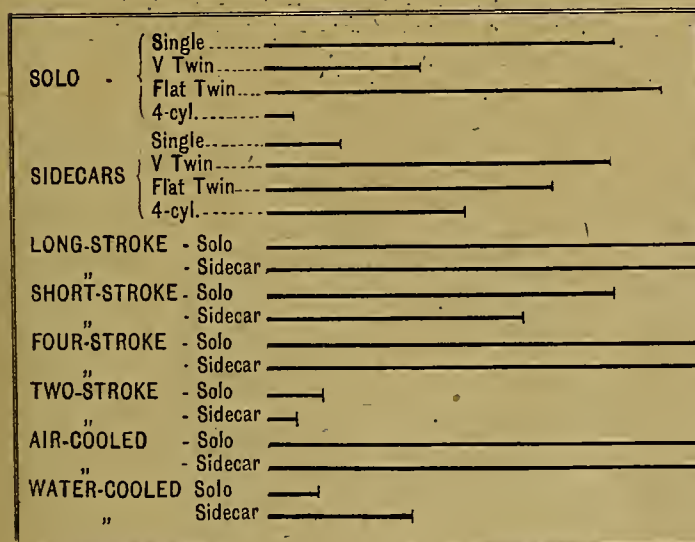

These figures are interesting, and show that 70% of the single enthusiasts favoured the $3\frac{1}{2}$ -4 h.p. proposition, which is not surprising considering the number on the road. This seems to contradict previous deductions, and rather shows that many owners of such machines are perfectly satisfied on the point of power. In the flat twin group also the 500-600 c.c. sizes together secured 77% of the votes.

To summarise solo engines we have the following table to show the proportionate values of the most important of the various types and sizes. From this it will be seen that, while in the flat twin group 20% voted for 500 c.c. and only 5% for 550 c.c., single cylinders of these sizes scored approximately 15% and 10% for 500 and 550 c.c. respectively. Therefore, taken together, the 500 and 550 c.c. flat twins scored 25% and the singles 25.7% of the solo specifications.

Summary of Solo Engine Referendum revealing the great popularity of the 500-550 c.c. sizes.

Types	Votes per 100.	C.C. Capacity.—Votes per 100 of all Solo Machines.									
		300.	350.	400.	500.	550.	600.	650.	700.	800.	1,000.
Flat twins	40	1.2	3.2	0.4	20.8	5.2	4.8	2.0	1.6	0.2	0.2
Singles	36	2.1	2.5	0.3	14.9	10.8	3.6	0.7	—	—	—
V twins	13	—	—	0.2	2.3	1.3	1.0	1.0	0.5	2.8*	3.1
Four-cylinder	5	—	—	—	—	—	—	0.10	0.07	0.08	0.17

* 750 c.c. capacity. Engines larger than 1,000 c.c. and unconventional types are omitted.

A CHART SHOWING THE PROPORTIONATE VOTING FOR VARIOUS TYPES OF ENGINES.

In the short stroke group is included engines with cylinders approximately "square" in their bore-stroke ratios

Summary of Engines for Sidecars, in which nearly Thirty per Cent. are 1,000 c.c. :

Types.	Votes per 100.	C.C. Capacity.—Votes per 100 of all Sidecar Machines.									
		500.	550.	600.	650.	700.	750.	800.	850.	900.	Over 1,000.
Singles	28	8.9	5.6	6.7	3.3	1.1	—	2.2	0.2*	—	—
Flat twins	16	0.9	1.6	1.9	0.7	1.8	4.5	0.9	0.6	0.7	2.2
V twins	35	—	1.7	0.7	2.8	2.1	9.4	1.4	—	4.5	13.6
Four-cylinder	20	—	—	—	—	—	2.4	—	0.6	0.8	13.8

* Several over 850 c.c. and under 1,000 c.c. suggested. Unconventional types omitted.

The sidecar engine figures are just as interesting, and taken separately according to type the following figures are obtained:

ENGINES FOR SIDECAR MACHINES.

Single-cylinders.

500 c.c.	32%	650 c.c.	12%
550 c.c.	20%	700 c.c.	4%
600 c.c.	24%	800-900 c.c. .	8%

Flat Twins.

500 c.c.	6%	750 c.c.	26%
550 c.c.	10%	800 c.c.	6%
600 c.c.	12%	850 c.c.	4%
650 c.c.	6%	900 c.c.	4%
700 c.c.	12%	1,000 c.c.	14%

V Twins.

550 c.c.	5%	800 c.c.	4%
600 c.c.	2%	900 c.c.	13%
650 c.c.	8%	1,000 c.c.	38%
700 c.c.	6%	Over 1,000 c.c. .	1%
750 c.c.	23%		

Four-cylinders.

750 c.c.	12%	1,000 c.c.	69%
850 c.c.	3%	Over 1,000 c.c. .	12%
900 c.c.	4%		

The 1,000 c.c. Engine.

From the foregoing it will be seen that a larger number of readers voted for the 1,000 c.c. four-cylinder engine than for a V twin of this size. This, probably, was to be expected when it is considered that the sidecar "4" must, of necessity, be over 750 c.c. owing to the smallness of the cylinders of an engine of lower capacity, whereas the twins begin the range of sizes at 550.

It should be noted that quite a number of specifications were suggested as ideal for dual purpose machines, hence the relatively large number of 500

Three kinds of engines which depart from the most general types. Ten per cent. of the voters for V twins specified the 90° type. Twenty per cent. of the specifications called for four-cylinder engines in the sidecar group and five per cent in the solo class.

c.c. singles which, before the war, was a very popular size for this purpose.

It should be recorded that nearly 10% of the V twin enthusiasts in both solo and sidecar groups specified a 90° engine.

Air or Water-cooling.

As will have been anticipated, only a small proportion of readers specified water-cooled engines, the percentage being 5% in the solo and 14% in the sidecar group.

We now come to the question of long or short-strokes, and we think this will cause surprise to the thinking reader, as the long-stroke scores heavily in both solo and sidecar groups. The surprise lies not so much in that so many should favour the long-stroke—the merits or demerits of the two types are still controversial. We are surprised because only a very small proportion of readers who sent in specifications can have had experience with long-stroke engines, since so few makes embody them.

Here we see evidence that those readers who have ideals have closely followed the technical articles in this paper, and that on the success of the Norton long-stroke engine and the theoretical advantages of the type many have specified long-stroke irrespective of the type of engine.

In the foregoing we have endeavoured to thrash out the question of engine types and power, and we think it will be agreed that the popularity with potential buyers of the respective alternatives is very clearly shown.

In subsequent issues we hope to deal with other points of specification in a similar way until the maker will have, for the first time, reliable data to assist him in formulating his policy in the immediate future.

OVERHAULING THE 2½ h.p. F.N.

A Few Hints for the Owners of this One-time Popular Machine.

By "F.N."

That the products of the F.N. Company found enthusiastic devotees is undoubted, but, perhaps, as an outstanding pioneer it has not received as much attention as it deserves. Here we give the opinion of an F.N. user as to the best method of conducting an overhaul.

The engine assembly Note the specially-shaped magneto shaft A, which can only fit in one position into the hole B in the timing gear.

A *PRIMA-FACIE* consideration with motor cyclists is that of accessibility. With the F.N. the fact that the cylinders cannot be removed without first taking out the engine from the frame may appear somewhat of a drawback, but the latter operation is, however, a remarkably simple matter.

The engine, complete with carburetter, inlet, exhaust pipes, and magneto, can be removed as a unit from the frame by withdrawing two long bolts that pass through the frame lugs and the cylinder casting, first having detached the exhaust lifter, petrol and oil pipes, and carburetter controls. It is also necessary to withdraw the bolt A (fig. 1), which allows the trusspiece between the rear of the engine and the gear box to swing clear.

It will assist matters if a strap is passed over the tank tube and threaded between the valve pockets and the cylinder (fig. 1), so as to take the weight of the engine, which may then be slid forward about an inch to bring the inner clutch member free of the front universal joint on the gear box.

The gear box can be removed in a similar manner by withdrawing two long bolts, but as it is hardly ever necessary to interfere with this, only a brief reference will be made to it later on.

Taking Down the Engine.

The magneto is detached by undoing three screws which hold its specially-shaped back end plate to the timing gear cover. It can be taken off and replaced without trouble, as the armature shaft is specially shaped and extended so as to fit into a hole of corresponding shape in the large 2 to 1 gear. Consequently if the valves are correctly timed the magneto must be also.

There is a paper washer between the magneto endplate and the timing cover, which should be renewed if it has become torn, and a groove will be observed in the timing cover leading from the large gear wheel housing to the edge of the timing case. It is important that this should be kept free from dirt, as its purpose is to lead away any surplus oil from the timing gear, so that it does not enter the magneto.

To take the engine to pieces, first take off the oil cap on the mainshaft between the flywheel and the crank case. This is a brass ring in two halves held together by a couple of small screws. Remove the timing gear cover with its paper washer, and it will be seen that the timing wheels are provided with a mark upon each, so that when retiming the engine it is only necessary to make the two marks come together to ensure the valves being properly set. Before removing the exhaust and inlet rockers, mark the former, so as to know which is which. If this is not done, they may be transposed in re-assembling, with the result that the timing is slightly varied.

The bottom half of the crank case can now be removed by undoing eight screws, permitting the complete crank and piston assembly to be withdrawn. Note that the locking ring of the inspection window in the sump is left-hand thread.

Fig. 1.—The tyre levers, lashed together and tightened with a tourniquet are to compress the clutch, thus affording more clearance in replacing

Unless new bearings are required, it is not necessary to remove either the flywheel or the small pinion. The former is keyed to the tapered end of the mainshaft, and secured by a right-hand threaded nut. If this nut must be taken off, it is best to make a special tool for the job. This can be made from a piece of tube of suitable bore, with four small pegs screwed in at right angles to each other at one end, so as to engage with the slots on the nut.

The Crankshaft Assembly.

The small pinion screws straight on to the other end of the mainshaft with a left-hand thread, and here again a special tool should be made on the same lines as that just described. On no account try to shift it with a pair of gas pliers or by using a punch against the teeth. The pinion and the mainshaft should be marked so as to ensure that the pinion is screwed on tightly enough when replacing. If it is not screwed back again to the same position, the timing of the valves will not be the same as it was before. A good tip for marking hardened steel is to draw a thin line across the parts in ordinary black paint, taking care not to touch it until it has set.

The crank pin is secured to each web by means of a plain taper and right-hand nuts, which are furnished with locking plates bent over the sides of the web to stop them from turning.

When reassembling the crankshaft, it is necessary, in the absence of a special jig, to put the assembly between the centres of a lathe, and accuracy can be secured by the use of a sensitive dial indicator. If the owner of the machine has not got these appliances at his disposal, it is better not to disturb these parts unless a new crank pin bush is needed. This bush is permanently fixed to the crank pin, and revolves in the hardened end of the rod. There is no gun-metal bush in the small end, the gudgeon pin merely taking its bearing in the hardened end of the connecting rod.

The best thing to do in the event of serious slackness in the small end is to soften it in the fire and reamer out a true hole somewhat larger than the previous

Overhauling the 2½ h.p. F.N.—

one. The small end can now be re-hardened, and a new gudgeon pin must be made, the bosses in the piston being reamed out to make it a nice driving fit.

The interior and exterior of the piston should be thoroughly cleaned of carbon deposit. If there is very much of this behind the rings they should be carefully removed and the grooves scraped out. If the valves require grinding in this can now be done, and when being refitted, the stems and guides should be well coated with graphite grease. The springs keep very cool and seldom require re-newing.

Whilst the engine is in pieces take the opportunity of thoroughly clearing out all oil holes and ducts, and after the necessary adjustments and replacements have been effected a liberal supply of clean engine oil must be introduced to all bearings before starting the reassembling process.

Fig. 2.—The bevel drive, wrongly alleged to be mysterious.

Examine the centre part of the clutch which carries the thrust cone and transmits the drive. This is secured to the centre stamping, which carries half the plates, by copper rivets. It sometimes happens that these wear slightly through harsh handling of the machine, and if they have become slack they should be replaced by new ones, or they may shear clean off in time.

The clutch should not require to be dissected, but this can easily be effected by undoing six long screws, allowing the two halves to separate.

The method of assembling the layers of outer and inner plates should be noted, and the plates cleaned and replaced.

In putting the engine together again it will be found a great convenience to remove the drain plug at the bottom of the lower half of the crank case, substituting an old sparking plug, which is happily of the same thread. The lower half of the crank case can then be held firmly in the vice by this means, and the rest of the engine built up on top of it.

The crank assembly goes back first, and it must be seen that the small dowel pin in the centre of each lower half of the main bearing housings engages properly with the corresponding holes in the main shaft bushes.

No washer of any kind is to be used between the two halves of the crank case, as these parts are machined so as to provide an excellent joint, and a washer

would prevent the main bearings being gripped firmly. Of course, both surfaces must be perfectly clean, and the eight screws well tightened up after the cylinder casting has been slid into place. The oil tap on the flywheel side may be refitted and the timing gear replaced.

Having replaced the rockers and the timing cover paper washer, the cover itself may be slid on, lifting the tappets with the fingers of one hand so that they clear the rockers. The small steady pins on the cover must not be bent or bruised or else the cover will not bed properly home.

The timing of valves and magneto should approximate to the accompanying diagram, although slight variation either way in the case of the valves is not important.

The engine is now ready to go back in the frame, and this process is simply the reverse of pulling it out.

On some machines there is not quite sufficient clearance to enable the front universal brass blocks to slide into the steel cage which screws bodily into the flywheel, and the inner clutch member should therefore be squeezed into the flywheel by the aid of a couple of tyre levers lashed together and tightened with a tourniquet (fig. 1). This has the effect of narrowing the flywheel the desired extra quarter of an inch.

The Wheels.

The only other parts of the machine which require inspection are the rear universal joint on the gear box and the bevel drive assembly on the rear wheel. The former can be inspected by releasing the snap fasteners on the domed dust cover, and any reasonable wear here may be neglected.

To take out the rear wheel, simply undo the nut on the other end of the long bolt G (fig. 2), and pull the latter straight out of the hollow axle; if the rear stays are now sprung lightly outwards with a screwdriver, the wheel will come clear away.

Probably both the small pinion and the hub bearings will need adjustment, and this must be done before the gears are checked over for correct meshing.

The hub bearings are adjusted in the usual way by the cone A and its lock-nut.

The small pinion is carried on a stub shaft which rotates in a double ball bearing. This bearing is housed in a

casing C, by means of which it can be moved nearer to or further from the centre of the wheel.

To adjust this bearing, take out the screws H which retain the dust cap K, thus exposing the rear cardan joint. Knock out the centre pin of this, and the adjusting cone and its lock-nut will be seen.

After these points are attended to, the bevels must be adjusted for correct meshing. Replace the rear wheel, slack off the nuts D, and take out the stud E. Now screw in the sleeve B until the gears are seen to engage for their entire length, screw in the stud E so that it engages in one of the slots in the body of C, and tighten up the nuts D.

The correct depth of mesh is governed by the sleeve nut F and its lock-nut.

Diagram of engine timing of the 2½ h.p. F.N.

Screwing this inward simply pushes the crown wheel out of engagement with the pinion, and *vice versa*. The gears are correctly meshed when there is about 1/32 in. between the top of an engaging tooth and the bottom of its corresponding space.

Note that removal of the back wheel does not alter any of the above adjustments, which rarely require doing.

If the overhaul is properly carried out with plenty of oil in the gear box and grease in the rear bevel case, quiet and smooth running is assured for the most fastidious owner.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

THE BARCELONA EXHIBITION.

Sir,—Mr. Harry Walker, a well-known representative of British interests in the motor trade in Barcelona, is now on his way over to this country. Mr. Walker is particularly anxious that British manufacturers should make a prominent exhibition of their productions at the motor car and motor cycle show to be held at Barcelona next March, to which you referred on December 26th last, in face of the certain and intense competition of manufacturers in enemy countries.

Spain is truly neutral in the matter of commerce, and the manufacturer who shows most enterprise—be he British, Austrian, or German—has an equally favourable opportunity of securing the business of the country. Mr. Walker already represents in Spain the interests of Thomson-Bennett, Terry and Sons, F.R.S. mechanical lamps, Sphinx plugs, Fuller accumulators, Millennium jacks, Harvey Frost and Co., Ltd., etc., and will be glad to get into touch with other British manufacturers of motor accessories on the occasion of his visit, with a view to exhibiting their productions at Barcelona.

Mr. Walker will arrive in this country within the next week or so, and remain until the middle of February.

Communications on this subject may be addressed either to the Sphinx Co., Bradford Street, Birmingham, or 107, Bishops-gate, London, E.C.2, and will receive prompt attention.

THE SPHINX MANUFACTURING CO.

POST-WAR MODELS.

Sir,—In the interests of the motor bicycle and its development, I feel I must register my keen disappointment on seeing advertised, with illustrations, so-called 1919 models of machines obviously still possessing comparatively antiquated specifications. In common with most other riders, I had looked forward to witnessing at the termination of hostilities many necessary changes in detail and design, the outcome of the drastic lessons of the war, instead of which what do we still see advertised? One of the best finished and most expensive machines shows forks of a comparatively old pattern, sprung for one direction of movement only. The footboards are unsprung, the old unsatisfactory type of rim brake is still employed; the carburettor, too, appears to be a pre-war production, well known for its simplicity and lack of refinements. (Apparently, the automatic single control apparatus has not been given the thought it deserves.) The illustration of another very popular machine still shows that crude type of transmission—the belt, with its annoying propensities for mud collecting, stretch, etc. Where is the British machine to be found embodying twist grip control?

Can it be that the unexpectedly sudden cessation of hostilities has caught most of our manufacturers napping, or is the reason for this lack of advancement due to the manufacturer possessing huge war and pre-war stocks, which, for financial reasons, he intends placing on the market before entertaining more advanced specifications? Must we patronise the American market to satisfy our requirements? VIC.

PETROL LICENCES.

Sir,—There has been such an excellent response to the Auto Cycle Union advertisements in your paper that I have been "snowed under" with requests for petrol licence application forms. To that large number of riders who have not had a prompt reply from this office, may I explain that the delay is really due to a cause which we all welcome—the impending extinction of the Petrol Control Department.

The conditions under which licences are issued are relaxed from day to day. This morning (January 2nd) it is agreed

that the official form of application should no longer be insisted on, and it is left to me to devise a simple form by which application should now be made by any rider applying through this office. The information required is the name and address, registered number and type of motor cycle, and quantity of petrol needed. The latter may be any quantity in reason.

Almost up to the end of the year licences were refused for any but business purposes, and quantities were strictly rationed. Then increased quantities of benzole as compared with petrol were announced. About this time the Petrol Control Department ran short of printed application forms, and it was not until after the Christmas holidays that official typewritten substitutes were obtainable. No sooner, in fact, had I prepared a circular letter to send out than it had to be scrapped owing to a further relaxation of the conditions.

All this work and worry could have been saved if the Government had simply cut the painter on January 1st, and had removed their control of petrol forthwith. They claim that this was impossible, as to do so needs fresh legislation. To which I reply that "where there's a will there's a way," and it should be, and is, just as easy to remove war-time restrictions promptly as we know, from experience, it is suddenly to impose them.

T. W. LOUGHBOROUGH, Secretary A.C.U.

PRICES.

Sir,—The matter raised by "Disgusted" in *The Motor Cycle* of December 12th regarding the sudden rise in price of a certain outfit without any apparent reason is certainly one which will make many prospective buyers think twice before placing an order for their next mounts.

A certain combination advertised in your esteemed paper on December 5th was priced £125, and a T.T. machine at £67 10s., whereas in your issue for December 26th the prices are £140 and £85 15s. respectively. From the wording of the advertisements these appear to be the identical machines advertised three weeks ago. Now, few machines, if any, can have been turned out in the last three weeks, therefore this increase in price—some increase, too—is being put on the same machines which were for sale at the lower price, although these have not cost the manufacturer one halfpennyworth more since the former-price was fixed.

Mr. Moore's so-called answer on this subject explains nothing. From what I have seen since being invalidated home a year ago the trouble with motor cycle agents has been to obtain new models, and not to dispose of them. In fact, from a recent review of the stocks of new motor cycles held by the leading agents, this undoubtedly appears to be the case.

H.L.I.

Sir,—I notice that "Ixion," in your issue of December 12th, says that motor cyclists must not be too optimistic about the price of motor cycles. He and others appear to hold the view that motor cycles of about 3½ h.p. will cost somewhere about £70 to £80, and that sidecar combinations will cost anything from £120 upwards.

Maybe they will, but those interested in the manufacture of motor cycles must realise that after the war America is sure to flood the market with cheap machines. They are quite capable of making a machine of even greater power for less money. As to the sidecar combination. For my part—and I think there are many like me—rather than pay £140, I shall buy a Ford for less money.

I do think it will be a terrible pity if the British manufacturer misses the trade because his prices are too high.

E. W. R. PETERSON.

THE THREE-JET BINKS CARBURETTER.

Sir,—There has been a great deal written about the "dead spot" in Binks carburetters. We have therefore tested this with an experienced rider in the saddle on the 10 h.p. four-cylinder Henderson. With the carburetter properly tuned for this machine we do not experience any "dead spot" whatever.

With the main jet two sizes too large, a certain amount of hesitation was noticed on opening from second jet to third, although it worked correctly on the pilot and second jet.

On removing the jet damper from the hole in the throttle barrel above the main jet, with the correct jets for proper running, hesitation was again experienced as before.

This proved conclusively that the cause of "dead spot" was by *incorrect jet setting and not any fault in the carburetter.*

We trust this will be of service to your readers.

We might add we are getting 75 m.p.g. out of so-called war-time "petrol" on this machine.

T. D. WHEELER, Lt.,

Instructor in Internal Combustion Engineering Khaki College.

J. PICKWORTH HUTCHINSON, Lt.

STREAMLINING.

Sir,—In your issue of November 7th "A Budding Pilot, R.A.F.," criticises my suggestions on streamlining a motor cycle. But, in my letter, I have not proposed to streamline a motor cycle. I only made mention of an *experiment.*

"A Budding Pilot's" criticisms are surely correct, but how does he explain the increase of speed? I believe the journal *La Science et la Vie* is much too serious and technical to make an untrue report of a test.

An experiment in motive power.

Perhaps at a very high speed the eddies formed by the plate or cone would be some feet behind the back of the rider, who would be in a vacuum. And why, if, according to "A Budding Pilot's" theories, the vacuum behind the cone is very limited, have many English D.R.'s fitted to their air intake a long pipe (generally an old horn part) to prevent the air intake being in the vacuum? I think it is a proof that this vacuum behind the cylinder (and the cone) is not like fig. 1 but like fig. 2.

Fig 1

Fig 2

In conclusion, I must add that experiments have been made

to transform air resistance in motive power by replacing the front cone by a suitable fan, geared to the wheel of a little

A device to prevent the air intake being in the vacuum caused by deflection of air in the cylinder.

car. And with a moderate wind in front the little car was able to go against the wind. Perhaps this is the streamlining of the future.

HENRI BOURSIAC.

Rouen.

STEAM MOTOR CYCLES.

Sir,—I beg to thank "Sapper Sub" for his interest in my steam cycle design, and have pleasure in replying to his questions herewith.

May I point out that in the present design the steam pipe, which is of solid drawn steel, is taken to the throttle valve from the steam generator without a joint. At the valve the joint is made with a copper-asbestos washer and a good large nut, and in this way the troubles from leaking pipe joints, as most feelingly forecasted by "Sapper Sub," will be avoided. There is no reason, however, why the suggested asbestos-lined sheet metal guards should not be fitted, for they will prevent undue radiation.

Now for the queries:

(1.) The feed pump is single-acting, with automatic delivery valve and mechanically operated suction valve. The barrel is horizontal, and the plunger is driven by an adjustable eccentric on the layshaft, geared 2 to 1 from the camshaft. By means of a suitably shaped cam operating the suction valve, the pump delivery is proportional to the steam cut-off at all speeds of the engine.

(2.) The condensate is returned to the tank by the pressure of the exhaust steam. Very little extra back pressure is caused by this method, which has the advantage of simplicity. It is a system which has been successfully used in practice.

Water is fed from the tank to the pump by gravity. The slight "head" assists the entry of the water into the pump.

(3.) I am afraid the word "automatic," which occurred in the summary, has led to a misconception. The plant is not automatically controlled, as I am of the opinion that such a system is not practical in so small a plant as is under consideration, and, consequently, a convenient hand control was designed.

(4.) The splash system of lubrication was included, and has been successfully used with a similar engine on a steam car. However, a method of pressure lubrication to big and little ends of connecting rods, camshaft bearings, etc., which avoids the presence of surplus oil in the crank case would be an advantage, the cylinders being lubricated separately through the cylinder walls or by introducing oil into the steam pipe.

(5.) No particular method has been provided for getting rid of condensed steam, but a small wall exhaust port at the end of the stroke on the under side of the cylinders has been suggested. These ports must be connected to the feed heater box by suitable pipes.

In a plant of this nature a high superheat must be obtained for starting, when the condensation will be very little, and here the small cylinder shows to advantage, since a much less bulk of metal has to be warmed up.

There is no danger with a poppet valve engine of forcing the cylinder cover off owing to collected water in the cylinder. Under such circumstances the inlet valve opens when the compression pressure exceeds the steam pressure and so acts as a cylinder relief valve.

If any further details are desired a perusal of the original article in the *Model Engineer* of April 11th and 18th will probably meet all requirements.

I shall be pleased to see any suggestions which "Sapper Sub" may bring forward, for I must confess to taking great interest in this subject.

THOS. HINDLE.

Sir,—I note from the Correspondence section of your widely read journal that the question of steam propulsion for motor cycles appears to be coming to the fore of late. I do not know much about steam cycles, but am somewhat familiar with steam cars, and your readers may take it from me that if a steam cycle can be built which will give even half as good performance as a steam car it will have the gasoline motor cycle outclassed every way, or, as "Ixion" might put it, "beaten to the wide!"

The following summary *re* the peculiar advantages of steam, from the pen of Mr. William Fletcher, the well-known British historian of steam road vehicles, may prove of sufficient interest to warrant publication:

"The steam engine may be stopped and started in an instant. It can be made to give any power from a few foot-pounds up to its full power, and is, in fact, what railway men call *more flexible* than any other form of motor. When a hill is to be mounted the four or five horse-power developed on the level road can be raised to twelve horse-power or more. Consequently, with the steam engine, steep hills can be scaled at rapid rate and all the difficulties attending bad roads can

he overcome without trouble. The steam engine is the simplest type of motor—and simplicity is a cardinal virtue—there are no gimcracks about it. Its few parts are understood by practically everyone. No special knowledge is required to attend or repair a steam engine. No breakages are likely to occur; but, should some little derangement take place, any small country engineer can put it right in a little time. The steam engine requires the smallest amount of attention . . . and experience teaches that a simple steam engine (single expansion) will give the smallest amount of trouble to the user.

"The steam engine is a well tried servant—no experiments are needed, and there are no patents to clear—its best details are perfectly free to all who choose to harness them.

"The steam engine works smoothly without jerk. It can be balanced so as to cause no vibration; both vertical and horizontal engines can be used. . . . The greatest economy may be secured by the following means. The engine will be run at fairly high speed . . . the steam will be slightly superheated to prevent cylinder condensation. The working pressure should be not less than 100 lb. per sq. inch. Expansive working is essential . . . and it should be possible to alter the range of expansion while the engine is running. . . . We would recommend the side-by-side compound type of engine." ("English and American Steam Carriages," page 68.)

It is only fair to point out that the above was written some fifteen years ago, when steam as a motive power for road vehicles was in a very much cruder state of development than we have it to-day. At least one of Mr. Fletcher's stipulations (i.e., where he speaks of steam pressures not less than 100 lb.) appears somewhat odd to-day, in view of the high pressures now found expedient and possible in modern steam car practice. Experience has likewise shown that the author's recommendation *re compounding* (as a means of procuring fuel and water economy) to be without good foundation; but in the main his statement of the case for steam is every bit as valid as if written yesterday. His reference to the steam engine as being entirely free from what he terms *gimcracks* I consider to be particularly happy, in view of the present-day trend toward twelve cylinders, magnetic clutches, hydraulic transmissions, electric gear-shifters, etc., in the "gas" car world.

So far I do not recollect having noticed any actual motor cycle specifications incorporating any of the above named "refinements," but unless the steam cycle comes speedily to our rescue I doubt not that motor cyclists will, in the course of time, be afflicted with each and every one of these trouble-making "gimcracks"—twelve cylinders, possibly, excepted. One enterprising American firm has already tried to give us electric starters, and rumour has it that another is now experimenting with an eight-cylinder engine of the V type.

Congratulations to Rev. T. Bayden Singleton for broaching the question of *steam cycle cars*. I concur, heartily, in the opinion that the same would be "an extremely interesting proposition." But why on earth mount the boiler as well as the engine on the rear of the chassis and thus make directly for *inaccessibility*? Have we not already had a plethora of this on our motor cycles?

Such a vehicle as Mr. Singleton has in mind, notwithstanding that he dubs it a "cycle car," would be, in fact, nothing more or less than a miniature steam car. I am working along this line myself, and if Mr. Singleton is thinking of building such a 'bus and cares to give his address and describe his requirements *via* these columns, I will undertake to see that he is supplied with some literature and information which may assist him in solving such difficulties as "housing the boiler" and kindred problems.

It is my opinion that if steam advocates and experimenters would only co-operate a trifle more freely in the exchange of views and information the development of both steam cycles and cycle cars would advance much more rapidly. In this connection I should say that I am given to understand that at least two steam motor cycles have already been built in England commercially. Will some one be kind enough to furnish a little reliable information regarding them? Who were the makers? What did the machines weigh? How did they run? Were they good hill-climbers? Are any of these 'buses still in service on English roads?

Since the above was written *The Motor Cycle* of October 24th has come to hand, and I note therein the steam cycle designed by Mr. T. Hindle. This machine looks pretty good

to me. Its one weak point, as I see it, is the boiler, or, rather, the steam generator. "Flash" boilers of many types have been tried out by American steam car builders. They were not considered a success, and have long since given place to *true* boilers of the "water content" type. In view of this fact, it seems questionable whether the "flash" steam system will prove entirely satisfactory on motor cycles.

Western New York State, U.S.A. SLIDE VALVE.

WHICH TYPE?

Sir,—I am sending a few suggestions made by a few knuts round the fire one evening during a discussion on "Which type?" I have tried to picture the sort of type it would be if some of them were adopted. Unfortunately, I have had to leave more than half of these comforts out, but I have tried to show the principal ones.

You will notice that the big single seems to be a favourite, with its long exhaust pipe, which has a joint in it to allow of easy cornering; also there is a small wheel on the handle-bars for the same purpose. The periscope would be useful, as well as necessary. A good searchlight must be fitted; this one takes 12 amps. 60 volts, similar to those we use in France. The generator is fitted at the rear of engine, under the oil tank. The machine is geared 1-4, not 4-1, so as to be able to get a good burst of speed. The back tyre should also lend itself to this end, and also to ensure

good hill-climbing. Overhead valves are fitted, also overhead carburetter. The question of petrol and oil capacity seems difficult, but this is a detail. It is a free engine, and there is possibly a kick starter on the other side.

You must excuse us getting like this, but we have not had a crash for two and a half years, and we are beginning to dream dreams. Still, we are thankful for small mercies, as the "Blue 'Un" turns up week by week, so we have our rides on paper. (CPL.) R. CHILDS, R.E.

Sir,—The question of "which type" of machine seems to be one of decided interest. We are always meeting single-cylinder, V twin and flat twin enthusiasts. Each type undoubtedly has its advantages. I do not think any of them will die out or become obsolete.

The single-cylinder will always remain as the general utility and reliability mount. It will always have a sphere as a fast machine (e.g., Norton, Rudge-Multi, etc.). Also, it is well known that a single-cylinder machine pulls a sidecar much better than any twin of the same power. The small flat twin mount is essentially a comfortable and luxurious machine. It has a good future as the "speedman's" machine (i.e., 500 c.c. A.B.C.).

The V twin is a very good machine for heavy combination work, and also has a remarkable acceleration. But I am rather inclined to think if a large flat twin engine could easily be put in a frame it would out the V twin.

One really comes to the conclusion that the single-cylinder machine is the one for general utility, the flat twin for fast riding, and the V twin for combination work. R.N.

or of leading Booksellers and Railway Bookstalls.

QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Clutch Adjustment.

Q. I have a Premier two-speed countershaft machine but cannot find means to adjust the clutch, which is slipping. How is this done?—O.E.

The clutch is within the gear box, and it is necessary to dismantle this to effect adjustment. Probably the plates are worn.

Magneto Adjustment.

Q. My motor cycle is a 1918 Triumph with an M.U. magneto. The other day I removed the contact breaker. Upon replacing it and examining to see if I had replaced correctly, I found a "fat spark" passing between the platinum points. (1.) I wish to know if such sparks are in order? (2.) How to separate these platinum points so as to clean them or hammer them, as recommended in "Hints and Tips."—J.C.S.

(1.) You will probably find that there is a condenser connection on the contact breaker cover; consequently, if the magneto is rotated with the contact breaker removed there is nothing to quench the spark at the platinum points. (2.) The platinum points may be cleaned by rubbing them lightly with a jeweller's file, which is inserted by pressing down the keel of the rocker arm when this is free of the cam. To hammer the points they have to be removed.

Irregular Running.

Q. I have a 1914 three-speed Triumph and sidecar. When the engine is throttled down to twelve-fifteen miles per hour I find it pulls irregularly, runs for a few yards regularly, and then slows up for a few seconds and picks up again. At the same time a hissing sound occurs from the crank case release in the centre of the pulley nut. This only happens as a rule when riding alone. With a passenger, or on a slight gradient, or against a head wind it does not often occur.—A.R.

It is by no means uncommon to find that an engine will run irregularly at speeds of fifteen miles an hour and under. This is nearly always due to the carburettor being in need of adjustment; either there are air leaks in the carburettor or induction pipe unions or too small a jet is fitted. The air, of course, must be closed, or nearly closed, when you are attempting to run slowly. The hissing sound you refer to is quite unimportant; probably it occurs all the time, but you only hear it when throttled down.

READER'S REPLY.

Straying Cattle.

May I call your further attention to the query on page 512 of your issue of December 5th re straying cattle? I would suggest that your opinion as given is not quite correct. It is clearly an offence for an owner to allow his cattle to be lying on the highway, and any person may prosecute, but it is doubtful, should "A.A." prosecute the owner of the cattle for lying on the highway, whether he would be in any better position in regard to his claim for damages. If I were in his position I should sue the owner of the cattle for damages sustained by his act, or default, in permitting his cattle, by lying on the highway, to form a dangerous obstruction to persons properly and lawfully using the highway, and I cannot well conceive the claim failing. I would advise a perusal of "Pratt and Mackenzie's Highways," also Section 5 of the Highway Act of 1864 and the cases thereon.—SURVEYOR.

Our legal adviser writes as follows: "Referring to the letter of 'Surveyor,' it seems to me that the opinion expressed by you in your issue of December 5th is the right one. In the case of Heath's Garage, Ltd., v. Hodges, decided in 1916, some twenty sheep belonging to the defendant strayed on to the highway from a field adjoining it owing to a fence being insufficient, and two of the sheep, having become separated from the others,

attempted to run across the road in front of the plaintiff's motor car, which was being driven at a reasonable speed along the highway, with the result that they collided with it and caused it to be overturned and damaged. It was held that the defendant was not liable in damages either on the ground of negligence or of nuisance to the highway, as, apart from his liability to be fined under Section 25 of the Highway Act, 1864, he was under no duty to fence his land so as to prevent his sheep straying on the highway. This decision of the Divisional Court was affirmed. This decision was on the lines of Cox v. Burbidge, to the effect that if through a person's negligent keeping of his own fences his horses or cattle stray on to the highway and do injury he is not liable unless they were vicious to his knowledge. The first-mentioned case appears to be one of the latest decided on this subject, and, although the point was a little doubtful, it would now seem that, although liable to a penalty under the Highway Act of 1864 for allowing animals to stray on to the highway, that Act imposes no civil liability in respect of harmless domestic animals trespassing on the highway. It appears to me that your correspondent has confused the liability of owners of cattle straying on the highway to be fined under Section 25 of the Highway Act of 1864 (not Section 5 as quoted by him) with the civil liability of owners."

Good Modern Second-hand Machines taken in part payment for any of the above.

Write for Catalogues or for any further information required to

GODFREY'S, Ltd., 208, Gt. Portland St., London, W.1.

PRICES OF NEW 1919 MACHINES.

Below we give a list of new 1919 models for which we have definite contracts already settled. The information as to prices and delivery dates is as given by the makers, and is as accurate as possible. Many of the makers reserve to themselves the right of altering prices without notice.

Our waiting list for the machines mentioned is now opened, and we are able to book orders on the following terms:

- £5 deposit with order; balance when ready for delivery. In the event of the price or delivery date altering, purchaser has the option of cancelling deal.
- We can lend you a second-hand machine to use until the new one is ready at the nominal charge of 10s. per week.
- We can take your old machine in payment, arrange a price now, and let you use it till your new mount is ready.
- We invite enquiries, which shall have our careful attention, and, if need be, advice.

NEW MACHINES FOR WHICH CONTRACTS ARE DEFINITELY FIXED.

Our selection of second-hand machines is still the largest in London. Remember our three terms of dealing, of which not one has yet been emulated by any other firm.

- Three days' free trial. Your money back at the end if not satisfied.
- Three weeks' option of exchange. Your machine taken back, and full price allowed, if wished, in exchange for anything else.
- Three months' guarantee—the same guarantee that the makers give.

'Phones: Hamp. 5392 and 4904.

Open till 7 p.m. and Sundays.

One minute Hampstead Tube Station.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd., and crossed** & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

MOTOR CYCLES FOR SALE.

ELECTRIC LIGHT

FROM MAGNETO.

A new method of obtaining light, sufficient for two lamps, from the extra current produced by magneto, which has been wasted so far. As soon as engine starts the lamps light. Perfectly simple and foolproof. No trouble in future to get your lamps lit. An accumulator is fitted into axle for use when machine is at a standstill.

AN UNSOLICITED TESTIMONIAL.

From *The Motor Cycle* of June 13th.
A 3 1/2 h.p. Sidecar Combination Enthusiast.
Recently Maj. Hodgson had his 3 1/2 h.p. Sunbeam sidecar stolen, but fortunately it was soon recovered. "I have," he tells us, "taken a passenger up Birdlip on it on second without a falter, and that was after a long, hot run. It may interest you to know that I have an F.R.S. lighting set run off the magneto. With the exception of the lamps it only cost £2 10s., gives a wonderful light, and is more reliable than any dynamo set I have ever seen."

NO LOSS OF ENGINE POWER. NO DAMAGE TO MAGNETO.

ELECTRIC ADAPTER

Price 4/9 each.

pare Bulbs 2/- each.

This is a small fitting to enable owners of gas lamps fitted with burners of the Rom type (round stem) to make their lamps into electric.

The "adapter" fits over the existing burner with a tight fit, and is connected to an electric wire and battery.

BRITISH HORN
Price 2/6

F.R.S. LAMPS, "BEAM" Works, Pershore Street, BIRMINGHAM.

American Supplies Co. Ltd.

FOR Magneto Repairs, spares, re-magnetising, British magnetos and dynamo lighting equipments, write or phone Streatham 2108. Established 1900.—Love-land Bros., Crescent Magneto Works, Norbury, London, S.W. [8078]

MAGNETO Repairs.—Send your magneto to Palmer's Garage, Tooting. Reply paid; quotation telegraphed on receipt. Quick, efficient repair guaranteed in from 2 to 6 days, usually within 24 hours.—Palmer's Garage, Tooting. [3980]

BIRMINGHAM.—Magneto repairs, rewinding, re-magnetising, and overhauling promptly executed; moderate charges.—The Electrical Trades Supply Ltd., 41, Gt. Charles St., Birmingham. T.A.: Motors, Birmingham. Tel.: No. 1601 Central. [1721]

THE Magneto Repairing and Winding Co., Established 1912. Manager S. T. Boon, late from the Bosch works.—Magneto repairs of every description. All repairs at lowest possible prices, and strictly guaranteed. We can mostly return them within 24 hours. We have several new and second-hand single and 2-cyl. magnetos in stock, all guaranteed.—The Magneto Repairing and Winding Co., 158, Seymour St., Euston, N.W.1. Phone: Museum 1158. T.A.: Kumsgracht, Norwest, London. [1032]

Enamelling OUTFIT No. 1.

For Motor Cycle and Sidecar.

INCLUDES an ample supply of absolutely everything you need to thoroughly renovate a Motor Cycle and Sidecar. Contents: Sponge, Chamois Leather, Rubbing Felt, Pumice Block, Robbialac Brush, Glass Paper, Cleaning Soda, Pumice Powder, Auto-Stopper, "Rusholine" Polishing Liquid, Robbialac Thinners, Robbialac Stopping, Mat, Gloss, Transparent; and Instructions. Price 35/-. Carriage extra England and Wales 1/6. Scotland and Ireland 2/-. Full particulars, including large Colour Card, from Jensen & Nicholson, Ltd., M.C. Outfit Dept., Robbialac Works, Stratford, London, E.15. Sole manufacturers of

TYRES.

BASTONE'S for Covers and Tubes.—Special clearance lines as below:

BASTONE'S.—26x2 1/2 Michelin 10/6, steel stud 20/-.

BASTONE'S.—26x2 1/2 Michelin Trident 22/-, Hutchinson Brooklands 18/-, Tourist Trophy 25/-, passenger 30/-, Kempshall 19/6, de luxe heavy 30/-.

BASTONE'S.—26x2 1/2 Hutchinson T.T. 27/-, passenger 32/-.

BASTONE'S.—26x2 1/2 de luxe heavy 32/-, Gaulois rubber non-skid 18/6, Shell heavy grooved 18/6.

BASTONE'S.—650x65 Henley heavy plain 32/6.

BASTONE'S.—Hutchinson tubes, 26x2 5/6, 26x2 1/2 6/-, 26x2 1/2 6/6, 26x3 7/6.

BASTONE'S, 228, Pentonville Rd., King's Cross, London, N.1. Tel.: 2481 North. [2237]

ECONOMIC Tyre Co.—Another delivery of new Kempshall clearance covers; goods carriage paid; on approval against remittance.

ECONOMIC.—26x2 1/2 Kempshall anti-skid 19/6, listed 48/8; Kempshall non-skid 35/-, listed 61/4.

ECONOMIC.—26x2 1/2 Kempshall non-skid 45/-, listed 72/6; 26x3 non-skid 75/-, listed 96/-; very heavy oversize for 650x65.

ECONOMIC.—26x3 Kempshall heavy anti-skid 45/-, listed 72/6; oversize for 650x65.

ECONOMIC.—28x3 Kempshall anti-skid 40/-, listed 79/8; fit American rims, only few left.

ECONOMIC.—The following are made by one of the best-known British manufacturers:

ECONOMIC.—24x2 1/4 heavy non-skid, for 2-strokes, 32/6, listed 45/6; complete with tube, 39/6.

ECONOMIC.—26x2 1/2 extra heavy non-skid, for 2 1/4 rims, 41/-, listed 60/3.

ECONOMIC.—650x65 extra heavy non-skid 43/-, listed 65/-; 28x3 extra heavy 45/-, listed 69/8.

ECONOMIC.—26x2 1/4 tubes 7/6, 26x2 1/2 7/6, 26x 2 1/2 x 2 1/4 8/6, 26x2 1/2 8/6, 26x3 10/-.

ECONOMIC.—26x2 1/4 fluted covers, wired on, 7/6, pair 12/6; good make, only a few left.

ECONOMIC Tyre Co., 137a, Lewisham High Rd., New Cross, S.E.14. Phone: New Cross 1393. [1826]

SECOND-HAND 26x2 1/4 Tyre, sound, 7/-; 26x2 1/2 7/-; tubes, 4/-.—Smith, 199h, King St., Ham-mersmith. [2163]

TYRES.—See Bancroftian Advertisement under Miscellaneous. Stelastic, Pedley, Kempshall, Hutchinson; extraordinary prices. [0845]

TYRES.

TYRES by Best Makers; nearly half present prices.—26x2 1/2 sidecar cover, 16/6; Kempshall heavy anti-skid, 26x2 1/2, 18/6 each.—Service Co., 292, High Holborn, London, W.C.1. [8747]

NEW Beldam Tyres, 26x2 15/-, 26x2 1/4 17/6, 26x 2 1/2 £1, 26x3 25/-; tubes, 26x2 1/4 7/-, 26x2 1/2 9/6; all new and sound.—Shelley, 76, Victoria Rd., Harlesden, N.W.10. [2144]

BURST Motor Cycle Covers Remoulded and made perfect; broken away heads remoulded; every job a success, or cash refunded; bursts from 3/6, returned carriage paid quickly.—Melton Rubber Works, Melton Mowbray. [X1400]

NEW Heavy Beaded Covers, 26x2 16/-, 26x2 1/4 25/-, 26x2 1/2 27/6; hutt-ended tubes, 26x2 1/4 8/6, 26x 2 1/2 9/-; endless tubes, 26x2 1/4 7/6, 26x2 1/2 8/-; sent approval carriage paid receipt remittance.—Palmer's Garage, Tooting. [9191]

TWO 26x2 1/2, to fit 2 1/4, Goodyear covers, not done 20 miles, 35/- each; two 700x80, to fit 650x65, Clincher Dreadnought covers, 45/- each; brand new one 28x2 1/2 Continental cover, 30/-; 6ft. 3/4in. Dunlop belt, 5/6.—See Heppelthwaite, Miscellaneous Column. [2216]

BELTS.

4 New Pedley Belts, 1in. and 3/4in.; 12/- each.—Buckmaster, 160, Boundary Rd., Walthamstow. [2154]

TANKS.

TANKS of every description; repairs, re-enamelling. Write for booklet.—Green, Water St., Blackfriars, Manchester. [0900]

TANKS.—Tanks any shape to order, repairs or enamelled; disc for motor wheels; general sheet metal work; lists free.—Attwoods, 86, Rosebery Av., E.C. Tel.: Central 12445. [9922]

PATENTS.

THE Inventor of the U. and I. Double sidecar (side-by-side) wishes to sell his patent, and would be pleased to hear from any person interested in same. There should be a very good market for such an article to-day. It can be attached to almost any make of motor cycle, and at the same time giving practically all the comforts of a car. Very suitable for people who have lost a limb.—S. Lloyd, Uffculme, New Barnes Av., St. Albans, Herts. [2067]

PATENT AGENTS.

INVENTORS' Advice and Handhook Free.—King's Patent Agency, Ltd., 186, Queen Victoria St., London. [5818]

CONSULTING ENGINEERS.

THOMAS PEERS, late Mechanical Transport, Advisory Expert, new or second-hand machines; consultations, examinations.—18, Lothair Rd., Finsbury Park, London, N.4. [2004]

REX MUNDY, after twelve years' all-round experience, offers unbiased advice on the selection of new and second-hand motor cycles and light cars; examinations and reports; vehicles bought and sold on commission; insurance; interview by appointment.—Temporary address: Box L8,425, c/o The Motor Cycle. [1976]

DON'T Purchase that new or second-hand motor cycle or cycle car until you have consulted me. There are many Lenins on the market just now. I can probably save you pounds. My experience of practically every make is at your disposal. Enquiries re date, value, repairs, etc., answered by return on receipt of P.O. 2/6 and stamped addressed envelope. Money returned if not satisfied.—Engineer, Violet Villa, Withers, Cambs. [1979]

INSURANCE.

FOR Insurance of all kinds (especially motor), apply, Ernest J. Bass, Insurance Broker, Bishops Stortford. [0693]

DREADNOUGHT Motor Cycle Policies at Lloyd's. Premiums from £1/7/6, payable yearly, quarterly, or monthly. Before insuring elsewhere, write for prospectus.—Rays, Ltd., 199, Piccadilly, London. [7734]

TUITION.

MOTOR Tuition.—The British School of Motoring, Ltd., gives the highest standard of training in driving, mechanism, and repairs for the lowest fees in England. Call, or write for full particulars.—The British School of Motoring, 6, Coveyry St., Piccadilly Circus, W. [0953]

AGENCIES.

GENTLEMAN with first-class connection, residing in Brussels (Belgian subject who speaks English), desires to represent in Belgium English manufacturers of cycles, motor cycles, accessories and tyres; 20 years' experience of the trade.—A. Watelet, temporary address 12, Dudley St., Luton. [2068]

SITUATIONS VACANT.

WANTED, good all-round mechanics, for car, motor cycle, and cycle work; healthy position (moorland); suit discharged service men. State age, wages, experience, and references.—The Yelverton Garage, Yelverton, South Devon. [1652]

DRAFTSMAN Wanted, used to motor cycle design, including engines, gear boxes, and general lay-out.—Write in confidence, stating age, experience, and salary required, Mr. A. V. Smith, c/o Chatter-Lee, Ltd., 74-84, Banner St., E.C.1. [X1750]

Government Motor Cycles.

IN our last issue we published an authoritative article on the disposal of surplus Government machines from a correspondent who is very closely in touch with all developments in this quarter. The conclusions to which our correspondent came were that bargain hunters would be in the main doomed to disappointment, and that the Government's best course would be to get the machines properly repaired by their makers at a reasonable cost and sold through the makers and their agents at a fair market price, and thus realise the full value for the property of the country. With this conclusion—we heartily agree.

The wastage of war is great enough in any case, and it is the obvious duty of all concerned to save the taxpayers' money wherever it is possible. There is, however, one class to whom special consideration is due, as we point out on another page. We refer to the men who in the early days of the war sold their machines to the Government at a valuation and enlisted in their country's service. It must be borne in mind that, although the price received was a fair one judged by 1914 standards, the same money would not purchase a similar machine in the open market to-day, for the scarcity and high prices of new machines at the present moment naturally react upon the second-hand market and cause a rise in value all round. Thus it is quite possible that a machine which had been stored during the war, provided that it had not suffered unduly from neglect or exposure, would fetch a better price now, in spite of its age—and motor cycles quickly become veterans—than if it had been sold in the year of its birth. This is partly because many machines have remained practically unchanged during the last five years, and partly due to the high prices and scarcity to which we have already alluded. It would then be a mere act of grace to give these men an opportunity of purchasing motor cycles equal to those which they owned

before the war at prices approximate to those for which they sold their former machines. Several correspondents have written to us upon this subject, and in one letter it is mentioned that a man may purchase from the army a horse to which he has become attached. The cases are not precisely similar, but if arrangements can be made in one instance it is also possible that they may be made in another.

The whole question of the disposal of war-worn motor cycles is an important one, and we are therefore dwelling upon it at some length. Further, we intend to keep the matter in view, and publish weekly the latest obtainable information.

Current Prices.

PRICES of motor cycles generally are 25% in advance of those of 1914, and there is a tendency among motor cyclists to consider them too high. Without any desire to make a plea of justification, we are, nevertheless, constrained to consider the present position in no way inconsistent with the times. As much as we wish to see motor cycles offered at pre-war prices, we are afraid it is more than can be expected, at least, until manufacturers have been able to adjust matters to the new conditions.

We can only guess the actual cost of labour and material represented in a motor cycle, but the price of all articles manufactured in trade is made up of material, labour, overhead expense, and makers' and retailers' profits. We know material and labour are up at least 100%, the third item, probably, not quite so much, although there is a great deal of labour in overhead expenses. We also know that profits are based on outgoings. So everything considered it does not appear that a 25% increase over pre-war prices is at all exorbitant, especially when it is remembered that in purchasing everything to-day the British public is called upon to pay advances in price considerably more than 25%.

IDEAS: Useful and Ingenious.

Sydney R. Jones

PRESERVATION OF INSULATING TAPE.

A RATHER good tip to prevent the annoying unravelling of the outer strands of insulating tape is to take a very sharp knife and make a number of light cuts across the diameter of the reel. It will be found that this effectually prevents the trouble.—R.H.B.

HAND CONTROL FOR TRIUMPH CLUTCH.

A HAND-CONTROL attachment can easily be fitted to the Triumph clutch-control pedal arrangement as follows: Procure an 18in. length of $\frac{3}{4}$ in. x $\frac{1}{4}$ in. flat iron and file the bottom end

An arrangement for controlling the clutch by hand.

to the radius of the pedal spindle. Drill a hole through the lever exactly opposite the bolt on the spindle arm and fit another bolt through the latter long enough to take the lever and the extra lever-retaining nut.—T. FAIR.

A NEW USE FOR A SPLIT PIN.

OCCASIONALLY a rod, rivet, or key must be inserted into a somewhat inaccessible hole, and it is often difficult to find a pair of pliers sufficiently small for the purpose. The illustration

A new use for a split pin.

shows how a large split pin and a washer may be used in place of the pliers. This device might be quite suitable for the purpose of replacing the small circular key used to secure the spring on Douglas valve stems.—*Automobile aux Armées.*

A14

USE OF BOX SPANNER.

I N some awkward positions where it is necessary to use a box spanner it is often found that insufficient leverage can be obtained with the ordinary small tommy-bar provided, or the spanner may

Adjustable spanner used in conjunction with a box spanner.

be too short or the bar too long or too weak. In many such cases it may be possible to turn the box spanner by means of an adjustable applied to the outside end as shown in the sketch.—L.A.B.

A CHEAP FRONT WHEEL STAND.

P R O C U R E three pieces of any hard wood, such as oak: (a) 34in. long by $1\frac{1}{2}$ in. square (for two uprights); (b) 2in. square by $1\frac{1}{2}$ in. thick (for supports marked X and X); (c) 18in. long by 8in. wide by 2in. thick (for base).

Take piece (a), find middle and bore $1\frac{1}{2}$ in. hole with brace, then cut into two for uprights. Tenon the ends to fit into mortises in base.

A simple front wheel stand.

Take piece (b), mark with line across the middle diagonally, and cut into two for supports to uprights at base.

Take piece (c)—base—make two mortises about 5in. apart or any width to receive front wheel.

Glue the parts together, and the result is a strong stand to hold the front wheel off the floor either for storing or whilst repairing punctures in front tube.

If used only for storing, it will help to preserve the front cover, which soon deteriorates standing on the floor.—W.P.J.

PETROL PIPE BREAKAGES.

A VERY useful little device has been sent to us by a reader which would, in case of breakage of the petrol pipe, save endless trouble. It is composed of a piece of flexible tubing having clamps at each end that can be tightened to any degree by means of butterfly nuts. The tubing is inserted on the broken petrol pipe and the clamps screwed firmly

A handy repairing device

down, making a petrol-tight repair. The illustration clearly shows the arrangement. This device is used on aeroplanes, and can be obtained of the large accessory dealers.

CUTTING STEPPED RINGS.

T H O S E who cut their own piston rings are usually content with the diagonal slit, not knowing how easy it is to make the better job of a stepped joint. The sketch shows how this is done. After carefully scribing the centre line, the vertical rough cuts are made, and the square portions filed out. The ring is then closed up and held between end

Showing a method of cutting a stepped ring.

plates, which are fixed on a mandrel consisting of a bolt or stud with two nuts on it as shown. The ring can then be lapped to finished size in the lathe.—V.T.L.

OCCASIONAL
COMMENTSBY
"IXION"

No Fear!

IN a recent issue I meekly warned novices not to make a South Sea bubble of the flat twin, hinting that it is not an easy engine to design, and that some catchpenny merchants may unload dud samples on an eager public. This well-meant warning has brought down upon me the rage of Mr. Leonard B. Henderson, who is familiar with all the flat twins now undergoing development, and is satisfied that they are all super-excellent. I have not the pleasure of Mr. Henderson's acquaintance, but pass on his encyclopædic panegyric to my readers.

Back to the 'Bus.

THE other week I described various niggling little aggravations which I had to bear with when Christmas leave sent me back to the pre-war 'bus. All of them were concerned with replenishment and other routine attentions. Let me now cite the machine's conduct as a goer. It had done about 12,000 miles in its distant youth, and had not been overhauled, even by my own clumsy hands, for eighteen months, or run for a year. Nevertheless, it started up at the first pluck of the back wheel, and proceeded to reel off 700 miles without an involuntary stoppage; and, when I somewhat timidly opened it out down three miles of straight, deserted moorland road, it pushed its speedometer needle well up to 56 m.p.h. and held it there.

The "Hogbus."

IT may be perfectly true that an up-to-date engine of 350 c.c. or so with a suitable gear box will do its mile a minute and climb any hill, but until human nature is regenerated some of us will ask for more than this. An ex-R.A.F. pilot, accustomed to 150 m.p.h., will not be thrilled by slamming open his throttle with about 3½ h.p. loaded up to about 4 cwt. There will always be a small but select market for a sheer "hogbus," capable of climbing at terrific speed and of furious acceleration on the flat. We have yet to see an ideal mount of this character. In theory it should add its special hallmarks to the usual desiderata of light weight, comfort, and reliability. In practice such speedrons are generally very uncomfortable and absurdly heavy. They are not unreliable in the ordinary sense of the word; but like most high-bred animals they are flighty and capricious. The 60 or 70 m.p.h. which may represent their best gait, is not always on tap. I am not sure that owners want it to be. In this class at any rate the rider rather enjoys chasing round in search of a lost 100 r.p.m. or so. Beyond question the single-cylinder types of "hogbus" have been worked up to a higher pitch than their twin-cylinder rivals. The T.T. Triumph, Rudge, and Norton may challenge comparison with any invaders in this class. But where is the standard-

ised 7 h.p. British twin hogiron? I know some very fascinating o.h.v. big Japs have been put out by various makers, but I think the market would stand a little pushing in such machines if they were developed on the lines indicated. Several American machines, especially the short wheelbase Henderson, were attracting many of our riders in 1914. I admit there are distinct objections to the unrestricted sale of very fast machines, but if they are going to be sold let them be British.

A Distortion Test.

NOW that joy-riding is again permissible, a clique of a few thoughtful friends may find some experiments with cylinder temperature interesting. The requisite apparatus consists of a mixed bunch of motor bicycles and a thermometer reading up to, say, 300°. (Two thermometers per machine are really desirable.) The aforesaid clique then proceeds to work the assorted engines rather hard, preferably by "scrapping" them along the road, though a full revs. climb on low gears or even a two minute run on the stand will suffice. Finally, the cylinder temperature is taken at various points, e.g.; on back and front walls level with the top of the piston stroke, on the valve chest and pulley or sprocket sides, over the exhaust and inlet valves, and at any other old pair of places which may occur to the experimenters. Ignore the absolute values, but pay special attention to the differences. Then consider mentally the advantages of an engine which shows the minimum contrast in temperature, e.g., between the back and front walls of the cylinder after a hard run on the road.

The Record Flat Twin.

ABOUT halfway through the war I became involved in a controversy with an engineer, who asserted that it was not possible to manufacture a satisfactory flat twin engine in the larger sizes, and implied that the 350 c.c. type approached the practical limits. This theory had no foundation in fact, but gentle Dora compelled me to argue in the abstract. I am now free to disclose that I waged that tantalising combat in close touch with a flat twin engine weighing 82 lb. and developing 52 b.h.p. This engine, I believe, was designed by Mr. Bradshaw in reply to an urgent demand from the War Office for a power unit to develop 40 h.p. and weigh not more than 100 lb. Plainly he more than fulfilled his share of the bargain, though the other apparatus essential to the projected stunt proved disappointing, and the "Gnat" was consequently stillborn so far as the war was concerned. Mr. Hawker actually attained 97 m.p.h. in horizontal flight with this two-cylinder engine (110 mm. x 120 mm.) fitted to a lilliputian scout. Perhaps we shall yet see a detuned "Gnat" on a cycle car chassis or in a world's record Brooklands bicycle!

THE WASTAGE OF WAR.

Unfit Army motor cycles, the majority of which will require a great amount of work expended on them before they are fit for the road. The machines were left in the state shown, the tarpaulins inadequate to protect them from wind and weather.

HUNDREDS of war-worn and discarded motor cycles, fit and unfit, are lying on Kempton Park Racecourse more or less exposed to the weather, illustrating the terrible wastage of material, labour, and money which war inevitably forces upon a people.

We have already written on the subject of war-worn motor cycles. An article, which appeared on June 14th, 1917, illustrated by photographs, showed hundreds of these machines; both their numbers and appalling condition called forth severe comments from many of our readers. Since the date of our article the Catford depot, which we mentioned, has been evacuated, and the Kempton Park depot, where there are still numerous machines, is in process of evacuation.

Now that the war is over, we frequently receive letters from readers asking for details as to the disposal of these remnants of the Great Conflict, and it is the object of this article to inform motor cyclists as to the actual position of affairs.

During the war Kempton Park Racecourse has been the distributing centre for army vehicles, as to this depot all new lorries, cars, and motor cycles were

sent direct from the manufacturers, thence to the mobilisation centre at Bulford, and from there direct to the various units Overseas. Kempton Park also received all the unfit vehicles, and lorries packed with damaged motor cycles are still arriving. As they arrive the machines are classified according to make and condition. Two-thirds of the number are usually fit for repair, and of these many—mostly of non-standard

makes—are placed in the motor cycle sales park. Non-standard makes are those which are neither Douglasses, Triumphs, P. and M.'s, nor Clynos, but such types as Sunbeams, A.J.S.'s, Ridges, Rovers, and other motor cycles made by well-known manufacturers which have been on home service. It is generally known that the army employs as few makes as possible so as to simplify the problem

Scrap and badly damaged machines, some of which are quite beyond repair

of spare parts. The classification of the machines referred to is only effected after they have been inspected by a board of officer experts.

New motor cycles in crates, ready for distribution, are placed under cover in open-sided sheds, and are not too well protected from the weather, as it can be seen that the outside machines are exposed to driving

The Wastage of War.—

rain or snow, and, even though grease is liberally applied to the bright parts, some evidences of rust are apparent. Machines which have been repaired in the army workshops are placed in crates and covered

magnetos at ridiculously low prices, but, despite careful enquiries, we have been quite unable to obtain any confirmation of this; in fact, we have been definitely informed that up to the present time none have been sold.

A panoramic view of the army machines under tarpaulin.

with tarpaulins. Motor cycles awaiting repair are in an open field, and as many as possible are placed under tarpaulins, but a vast number of unfits are without any protection whatever. It is the sight of this huge number of motor bicycles left day and night, winter and summer, exposed to all the vagaries of an English climate, that has led to so much criticism, and in defence of this it is argued, and not without reason, that most of them have been rescued from the battlefields of Flanders and elsewhere, where they have been exposed to rains other than

The sales park consists mostly of makes other than army standard. On the outside thereof there are crates of machines which have been rebuilt or repaired by the army, and when the war was on these would have been used for home service. In the centre of the park are the unfit machines, mostly denuded of saddles and magnetos, classified according to makes. The first notice reads: "4 Rover, unfit H.S., no more to be placed here," and the other notices are of a similar nature.

The disposal of army motor cycles is in the hands of the Surplus Government Property Disposal Board, 6, St. James's Square, London, S.W.1, and on enquiry there we learned that, pending the formation of a definite scheme for the disposal of army vehicles, the Board has temporarily suspended operations. Previously, anyone

(Top) Motor cycles ready for sale and classified according to make. In the rear are new and rejuvenated machines in crates.

(Bottom) New and uncrated motor cycles. The great majority of these are Triumphs

and besides those of heaven. They have often been literally buried in the ground, and so a month or two's extra exposure will do them no further harm. Unfit motor cycles, as they are called, are those which have suffered severe accidents, have been run over and ditched, or have been hit and severely damaged by shell or machine-gun fire. We saw several interesting cases of the latter during our visit.

From time to time rumours have reached us that derelict army motor cycles have been sold minus

could apply to the Board, get a pass, and go down to Kempton Park to inspect the vehicles. Any reasonable examination was permitted, but, of course, no dismantling of any part could be allowed. We give a list of some of the machines in the sales park: 24 fit Rudges, 86 fit Zeniths, and numerous unfit machines, of which we may mention 17 Sunbeams, 96 Scott s.c. combinations, 36 Scott solo machines, 99 Zeniths, 23 Premiers, and 33 Rovers.

The Wastage of War.—

The question is—when will the Government move? The market is excellent now; second-hand prices are higher than they ever will be again, and, despite arguments to the contrary, the goods are depreciating. A few months hence, when new motor cycles will be available, second-hand prices may drop, so no useful purpose can be served by further delay. There was an auction sale of certain Kempton Park motor vehicles last week, but no motor cycles were included, and why this was the case no one apparently can give a satisfactory answer. It is quite time something was done. It seems clear that the R.A.S.C. has done its best. During the latter part of the war it has had to struggle along with men of low category; it has asked for the material with which to build sheds, but none was granted, as all that which was available was needed for the R.A.F.

The Disposal Board is alive to what is required, but can get no answer from the Ministry of Supply, and so it seems that this body is really to blame.

It has been suggested that it would be to the interest both of the general public and the trade if the manufacturers were to buy these machines, restore them to new condition, and sell them under a guarantee, and we understand that the manufacturers have been approached, but have not made an offer which the Board could accept. The whole question, therefore, remains in abeyance. The matter is an urgent one, as the motor cycles are bought from funds supplied by the taxpayer, and he rightly demands that they should be disposed of in the most advantageous manner.

A shell-battered motor cycle which might well form one of the exhibits in the projected National War Museum.

The motor cycle manufacturer and rider, too, have a right to be considered. If the machines were released at once before the manufacturer is in a position to supply, many riders would be able to obtain machines who otherwise would have to wait. This would not interfere with the sales of manufacturers, for at the moment there are few who have machines for sale, and it will be some time before they are abreast of their orders. If, however, the Government machines are allowed to lie idle until the manufacturers are able to produce in quantity it is quite possible that the trade in new machines will be damaged. Moreover, the prices obtained will be much less than if the machines are sold without any further delay. At the present moment second-hand prices are high, but this will not continue indefinitely.

There is in our opinion one class of rider who should have special consideration, viz., the man who enlisted as a D.R. early in the war and sold his machine at a reasonable valuation to the Government. It seems to us a mere matter of justice that such a man should have an opportunity of replacing the machine which was devoted to the service of the country at a similar price, instead of having to pay out a much larger sum of money to obtain an equally sound machine. This does not mean that we think that the Government should give away its property at prices far below their actual value—the difference having to be made up by the taxpayer—but only that the class of rider to whom we refer should receive the consideration which is obviously his due. He must not expect a bargain, but a fair machine at a fair price.

PAST AND FUTURE.

ARE manufacturers awake to the coming condition of things? Are any of the firms who are really in a position to produce the right vehicle by the thousand making any preparations to do so? The cycle car has not proved a success in the past simply because it has lacked the support of those influential firms who might have made a success of it. It was left to little experimentalists in back street factories, and in the one or two instances where mechanical success crowned the efforts of reputable firms, financial success was impossible owing to the bad name the vehicle had won at the hands of others. Light, flat-twin engines are now being made which render the cycle car more practical than ever before, and in itself it is a practical type of vehicle, demanding only commonsense methods and proved and well-tried principles. There is no need for new departures, absolute simplicity and proper weight distribution being the two fundamental points. Who is to be the first to take this gigantic market of the machine for the multitude?

CHINOOK.

ANOTHER GUDGEON FIXING DEVICE.

MANY and varied have been the methods devised to secure the gudgeon in pistons and prevent endwise movement which would be liable to cause scoring of the cylinder walls. The makers of

The Vermorel gudgeon pin fixing.

the Vermorel car have an idea which is rather unorthodox, and consists, as shown, in passing a locking pin through the gudgeon boss and pin from the top of the piston crown, into which it is screwed. This method appears to be both simple and reliable, but we should anticipate difficulty in extracting the locking pin after any considerable exposure to the heat of the combustion chamber.

Electric Lighting by Dry Battery.

Points to be Considered in Choosing an Electric Lighting Outfit.

The advantages of dry cells over accumulators are set forth in the following article, which also shows that when illumination is only required for short intermittent periods a dry battery even scores over a dynamo lighting set.

DESCRPTIONS of, and experiences with, electric lighting sets have appeared in *The Motor Cycle* on several occasions. Up till now, however, the writer has only seen reference to those of the dynamo-cum-accumulator and the solo accumulator types. Lighting by dry cell seems to have been almost entirely ignored, and as this type of battery has much to recommend it, it is only fair to give it an innings.

The great merit of the dry cell is that, once it is installed and wired up, it requires no further attention whatever during its life. It is absolutely reliable, as witness its use to operate switchboard controls on large central station power plants. When it is run down the cost of a replacement is not a serious item—in fact, the outlay is very often less than would have been incurred in paying for the charging of accumulators, in cases where no dynamo is fitted, taking both types as in use for the same period.

Attention Required for Dynamo Lighting Sets.

Even when a dynamo lighting set is properly installed, it requires a certain amount of attention if it is to give good results. During the summer months, for instance, the accumulators must be discharged and recharged at regular intervals unless much night riding is indulged in. On a motor cycle an occasional discharge must be specially arranged for either by switching on the lamps during the daytime or by connecting the accumulators to a resistance taking a known amperage.

It is when lights are required only for short distances that the virtues of the dry cell are chiefly manifest. It can—if of reliable make—be left unused for long periods without deterioration. This cannot be said of the accumulator, which must, for its health's sake, be charged every four or five weeks whether used or not.

Four-volt and Six-volt Sets.

The writer has two dry cell sets in use—one six volt on a Rudge and one four volt on a Douglas. The batteries are both Volex, obtained from Messrs. Ward and Goldstone, and have given satisfactory service, particularly the six volt cell, which has been in intermittent use for nine months, prior to which it stood on a shelf for three months until time could be found to fit it up. It is still going strong, and, judging by the light given by the lamps, has lost little of its capacity. The four volt cell has not done so well; it has only been in use about three

months, and is already showing signs of falling off. It will still, however, furnish sufficient current to supply what light will be needed during the spring and summer, thus giving nine months' lighting for a cost of 6s. Neither battery has had any attention whatever—in fact, the lid of each case has never been removed since put on in the first place.

The flexible metallic cable can be clipped to the head of the machine in the tube through which the leads are run. When disconnected the terminals of these leads are clamped under a convenient thumbscrew. This equipment is shown fitted on the writer's Rudge.

The Boon of Electric Lamps.

Those motor cyclists who up to now have only used acetylene lamps can have no idea what a boon it is to be able to wheel the machine out of its shed and for both lamps to spring into light with the touching of a switch. The time taken to light acetylene lamps, including that spent in cleaning and recharging the generator, is in many cases just about the same as that taken by a rider whose machine is equipped with electric light in travelling the three or four miles to his destination. In addition, a little ordinary care taken in the initial wiring up makes the possibility of roadside stoppages on account of failure of light very remote.

The set as fitted to the Rudge is shown in the first illustration, and it will be seen that its fitting up is somewhat unique, inasmuch as the battery and head lamp are both mounted on one common bracket. This bracket was made out of a P. and H. set by cutting off the lugs which normally carried the acetylene generator and brazing a strip of 14 s.w.g. sheet steel, $\frac{3}{4}$ in. wide, on top of each arm, to form a platform for the battery box, which is secured to the platform by a number of wood screws.

The battery box is made from mahogany, $\frac{5}{16}$ in. thick, with a loose lid held down by hook catches, the battery being tightly packed in with horse hair.

An Unusual Position for the Battery.

The complete unit is carried on the handle-bars, and, though at first sight it appears rather ungainly and top heavy in this position, no trouble has been experienced with it on this score. It must be admitted that on greasy roads its weight can be detected, but it has never caused a skid, and it is very convenient to be able

to remove head lamp and all during the summer months by simply undoing two nuts and slackening off the milled nuts which secure the wire leads running to the tail lamp.

Double wiring is used throughout, thus eliminating a common source of trouble with low voltage sets due

The wiring of the dry cell electric lighting set.

Electric Lighting by Dry Battery.—

to faulty connections at clips and suchlike places when the frame of the machine is used as the return circuit.

A square-shaped sump or well on the bottom of the battery box serves two purposes; it is a cover for the switch, which is of the miniature tumbler variety, and it also carries the terminals whereby both lamps are connected to the one battery. The wiring diagram will make this clear. A hole is cut in the bottom of the sump just large enough to allow a finger to be inserted to operate the switch knob.

Little Outside Wiring.

Outside wiring is reduced to a minimum. One short length of twin workshop flex, carried in a piece of rubber tube for extra protection, permanently connects the head light to the terminals previously referred to. The twin wire to the tail lamp is carried in a length of flexible metallic tube. The leads from the battery to the switch, etc., consist of the inner members, thinly rubber insulated, of twin flex after all the cotton covering and serving has been stripped off. They are run in grooves cut in the inside of the battery box, and are kept in place by a strip of thin leather glued over the top of them.

Both lamps have been converted from acetylene. The head lamp carries a 6 c.p. small bayonet bulb taking 1 ampère, and the tail lamp a 3 c.p. small screw bulb taking $\frac{1}{2}$ an ampère. All ventilation holes in the lamp body have been stopped up, to exclude dust, by brown paper stuck down with black spirit varnish.

The paper is well painted over with the same preparation. This makes quite an efficient job, and by suitably snicking and cutting the paper at the edges it can be made to fit quite snugly round the curves of the lamp.

When the top cowl was removed, a hole was left in the lamp top which was too large to seal satisfactorily with paper, so a sheet of aluminium had to be beaten to shape and riveted in place.

Reflector Experiments.

The head lamp was fitted with a Bausch and Lomb lens mirror. This was retained, although its efficiency is not so great as that of the parabolic type of reflector usually fitted to electric lamps. This is due to the former not collecting all the rays of light from the white hot filament of the bulb which the latter, owing to its position, does. To obviate this loss as far as possible the experiment was tried of silvering over—as a mirror—the front half of the bulb, so that the rays which would have passed straight from the bulb through the front glass are thrown back on to the lens mirror and thence projected forward. The experiment has been quite successful, and, considering the low candle-power of the bulb, the illumination obtained is quite good; 20 m.p.h. on open country roads can be safely indulged in.

The bulb and its holder, of course, are fitted vertically in the body of the lamp, and their shadow can be clearly seen on the obscured front glass when the light is on. There is, however, no noticeable blind spot in the beam caused thereby. F.B.S.

COMFORT IN SIDECARS.

COMFORT in sidecars is almost as important as comfort on the saddle, and any device which makes for the benefit of the lady passenger will always be fully appreciated, and, incidentally, add to the popularity of the sidecar.

centre tax to the utmost any springing device of a sidecar or car, and Messrs. Grindlay must be congratulated on producing a springing system that has to be tested to be fully appreciated. No abrupt shocks could be felt even when passing over the worst of pot holes, a gentle rise and fall being the only motion noticeable. The body design is very pleasing. Aluminium panels and large car type mudguard give a distinctive finish which will appeal greatly to feminine taste.

The Grindlay double sprung sidecar described in our issue for December 5th. Note the semi-elliptic springs on each side of the wheel and the separate cantilever springs supporting the body.

A short run in the "Grindlay" proved that it is possible to construct a sidecar giving comfort equal to that of a well-sprung car; in fact, it was far more pleasurable than riding in some cars. The roads in a munition

OPINIONS.

Notes on the Past, the Present, and the Future. By Prominent Men in the Motor Cycle Movement.

THIRD SERIES.—Comments of Designers and Others well-known to Motor Cyclists.

From Maj. T. W. Loughborough, Secretary of the A.C.U. and the British Motor Cycle Racing Club.

THE fascination of motor cycling, compared with any other form of locomotion—yes, flying included—has been explained, but the explanation, whatever it is, does not interest me so much as the fact that, unlike most of those pleasures which we, as a nation, are credited with taking so sadly, it does not lessen with use.

Having been debarred from the said road for so long, or, at least, being strictly limited to that portion terminated by home and the railway station or place of business, the fascination of motor cycling—free as the air—will, to us old-stagers, be redoubled. And for every pre-war motor cyclist reviving his old interests there will be more than one new recruit: men who have noted, during their service abroad, the marvellous efficiency of the D.R.'s mount, and others at home, men and women too, who have

saved up their war wages with a wise eye for the future. Given anything like reasonable conditions as to fuel supplies and the prompt removal of war restrictions, and I foresee a demand for new machines that will severely tax our manufacturing resources. Indeed, there is a danger that, in striving to meet this demand, the trade may so concentrate on pro-

Maj. T. W. Loughborough

duction pure and simple that it will lose sight of the fact that, of all classes of motor vehicles, the motor cycle is perhaps the most capable of improvement.

Possibly I am presumptuous; and if I could be taken at my word the result would prove that the trade is not so short-sighted after all. Nevertheless, I do feel that, if I were given a free hand in the drawing office and experimental department of one of the leading makers, I could remove some of the reproach contained in my last paragraph. The power unit and transmission as such would not worry me. I should approach the task from the owner's, and not the engineer's, point of view. I should keep before me a mental picture of the two machines I own at present. I should try and incorporate in my design everything that the rational driver requires, and not leave it to him to find room to attach anything—more or less permanently—afterwards. I should be ashamed if I could not hose down and polish up my completed product in less time than it takes my neighbour to clean his car.

From Mr. Tom Silver, Pioneer Rider at Home and Abroad.

PROBABLY design is the bedrock upon which every practicable measure of reconstruction will be founded, and it is certainly not a process which can be delayed.

In pre-war days, before the use of the motor cycle became as prevalent as it is to-day, manufacturers had not considered the possibilities of pressed steel and die castings in construction. However, it has now become evident that these will play an important part, and no doubt the trouble will not be in the disposal of the product, but in the production, where cheaper and quicker methods should be looked for, especially in making a medium or low-priced outfit.

In 1919 it should be possible to purchase a better outfit at the same cost as in 1914. It is plainly evident to all that the experience gained during the war can be adapted to replace the conventional construction of a motor cycle, and so enable manufacturers to make their product of the design required, viz., a foolproof, weatherproof, sprung frame.

From Mr. A. J. Wilson, an Early Motor Cyclist.

AT the end of twenty years of motor cycling I am still hankering after a really lightweight runabout motor cycle upon which to do short rides for which it is not worth while to get out the car—a machine to be carried inside an office door and forgotten until wanted for an immediate journey, but then dependable to start without trouble; to require little more attention than the push bicycle, so long as it be not over-driven.

Mr. A. J. Wilson.

From Mr. J. E. Greenwood, Chief Engineer, John Marston, Ltd., Sunbeamland.

THERE is one feature of the post-war trade that has struck me very forcibly. It is the absence of anything indicating which is likely to be the most popular post-war model.

In pre-war days there is no doubt whatever that the $3\frac{1}{2}$ h.p. single-cylinder machine was far the most popular machine on the road. The chief reasons for this were that it was the most highly developed type, and the type that was being turned out in the largest numbers, by the largest number of makers. Another strong argument in its favour was its unassailable position as the double-purpose mount pre-eminent.

If past experience is any guide to the future the most popular post-war model will be the double purpose machine. Assuming that this is so, we are faced with the question of what type of machine it will be. There will be the ever-popular single, the V twin, and the horizontally opposed twin all fighting for premier place. For solo work both the V twin and the horizontal twin are delightful to ride, and certainly more sweet and vibrationless than the single; but when the machine has to tug a heavy

sidecar about there is, to my mind, nothing to compare with a good single. I am, of course, speaking of machines of about 500 to 600 c.c. I have ridden a good many twins of about 600 to 650 c.c., and although they are very nice to ride, they seem to lack the pulling powers of a good 500 c.c. single. The chief reasons why the single is the ideal double-purpose machine are: It is very easy to keep in good order, it will (if reasonably handled) run a very long time without requiring any adjustments or repairs, and it is probably the most durable engine made.

Regarding the most popular size of engine for the double-purpose machine, some people think that the $3\frac{1}{2}$ h.p. is not quite powerful enough; but when one considers the really wonderful performances put up by standard $3\frac{1}{2}$ h.p. sidecar combinations in open competitions there does not appear to be any necessity to go to a larger size engine.

The consideration of engine sizes brings to mind another matter about which there has been much controversy. I refer to the merits (or otherwise) of the long stroke engine. Personally, I do not think there is much to choose between a so-called long stroke engine and an engine having equal bore and stroke. My reason

Mr. J. E. Greenwood.

Opinions.—

for this statement is that, within the limits of the average motor cycle engine, it is impracticable to use a stroke-bore ratio higher than about 1.3 to 1.

Although theoretically there is an increase of efficiency with a long stroke, the real practical gain is so small when the ratio is limited as above that it is not worth arguing about.

From Mr. Leonard B. Henderson, A.M.I.A.E.,
Managing Director of Henderson Sidecars.

THE matter of reconstruction, in my estimation, will be a colossal task, and great industrial and commercial questions will have to be settled by the new Parliament.

Britain for the British, and British markets for British industries, should be an outstanding feature in future, this being the biggest question in the reconstruction of industry. In the past the British markets have been flooded with motor cycle fittings, accessories, and other goods exported by Germany and her allies, most of which had been manufactured with the express purpose of deceiving the buying public. The unwary have purchased the "goods," no doubt under the impression that they were British (owing to the inefficiency of the Merchandise Marks Act), only to find after short use that their purchases were worthless and unfitted for the purpose intended. Can anyone say that that the British standard of quality has ever been equalled? Impossible.

Therefore, it is the business of the new Government to instil into the public at home and Overseas the sterling qualities of British goods.

I feel that the motor cyclist should really be protected against the allurements of cheap and shoddy articles, whether produced in a foreign country or here in England. In the period to come I am convinced that all such shoddy, badly

Mr. L. B. Henderson,
A.M.I.A.E.

designed, horribly made, motor cycle goods will be eliminated owing to the fact that the motor cycling public are getting more educated to the belief than ever that a good sound article is always worth a little extra.

That the war has taught the nation something applies to industry also, and the motor industry comes in first. After-war motor cycles, sidecars, accessories, etc., will differ greatly from the old. Brains have been far from stagnant, and each day we hear of great inventions which show much promise, and which no doubt will, more or less, cause a revelation in statistics. New engines, on well tested and highly efficient aero engine lines, are already with us, and promise to end for all time the defects of pre-war design.

It is quite impossible in this short space to detail the wonderful and varied developments in metallurgy during the past four years, this great advancement having

an inestimable bearing on the extra efficiency of post-war motor cycles. Unbreakable steel of a special alloy settles at once all valve troubles of the past. Steel of remarkable tensile strength will give double strength for half the weight compared with the old type used. Problems such as rust, corrosion, weather effects, etc., will be bogies of bygone days.

In conclusion, I do not think there is any further need for us to sing "Wake up, England!" in matters pertaining to motor cycling.

From Mr. Hugh Gibson, of the Clyno Engineering Co.

CHEAPER machines, more weather-proof machines, and an adequate supply of fuel, are three of the main essentials necessary to increase the popularity of motor cycling.

If British manufacturers are going to utilise to the full the increased facilities for quantity production, then, once we get over the reconstruction period, the output of motor cycles will be enormous, probably exceeding 150,000 per annum.

Fewer models and increased production mean cheaper machines for the public (and, incidentally, higher wages for the worker), and a policy of "one firm one model" will no doubt be adopted in the future by all the most progressive concerns in this country.

By standardisation and concentration on one model, and by production in large quantities, motor cycles will be produced very much cheaper than ever they were in pre-war days; but until the cost of material comes down to a more normal level the full benefit of up-to-date quantity production methods will not be realised.

Before long we may probably witness the amalgamation of a number of firms making a similar type of machine.

Suppose, for example, that the Triumph, B.S.A., Rover, Sunbeam, Norton, and Singer companies joined forces and concentrated on the production of one model, each firm making component parts for, say, 50,000 machines. An attractive model could be produced to sell at 30 to 35 guineas, and the price would create the demand and enable these firms to dispose of a much larger number of machines collectively than ever they could hope to do individually.

Amalgamation, co-operation, and concentration on these lines amongst the leading sidecar manufacturers would result in the production of a high-class standardised sidecar outfit that could be sold at 65 to 70 guineas. The output, of course, would be enormous, but the demand would also be enormous; whilst by these methods American competition could be met and defeated in most markets; and instead of our Colonies taking 90% of American-built machines, they would be glad to take 90% British.

Mr. Hugh Gibson.

From Mr. John Duffy, A.M.I.A.E., Designer and Director of the Valveless Two-stroke Engine Co., Ltd.

THERE are two features in motor cycle design which, to my mind, have not in the past received the recognition they merit.

The first of these is the loop frame. For years now the conventional practice has been to make the engine part of the frame structure, in which position it helps to support the load in addition to propelling the machine.

This is admittedly bad practice, and yet convention continues to override efficiency.

The frame should be of a structure complete in itself and capable of supporting the load whether the engine is in position or not, and there is hardly a type of motor cycle, either two-stroke or four-stroke, which would not benefit by the adoption of this principle.

Among the advantages of the loop frame are ease of assembly, high ground clearance (when used in conjunction with the outside flywheel), and an engine free from frame stress. This last is of particular importance on two-stroke machines, where the crank case joints require to be gastight.

The second feature is the outside flywheel.

The virtues of this over the usual type are so obvious as to require little emphasis from me. Accessible and adjustable big end bearings, better acceleration, smaller crank cases, less weight, and cleaner engines are patent to anyone who gives this subject a thought.

Why the outside flywheel should, almost without exception, be left to makers of flat twins and two-stroke engines is more than I can understand.

From Mr. F. H. Bluemel, Managing Director of Bluemel Bros., Ltd.

I AM pleased to take the opportunity afforded me by the Editor of *The Motor Cycle* to say a few words direct to the users of motor cycles and accessories, particularly relating to present and future output and prices.

I am afraid many have thought that immediately war conditions terminate the supply of goods will be renewed in quantities similar to those that prevailed before the war, and at prices somewhat approaching those of that period; but no doubt, by now, the majority have already been made to realise the impossibility of this.

In the first place, raw materials are not yet any cheaper than during the war, and, as far as I can see, there is no appreciable increase in output. This will no doubt be made shortly; but a great improvement is necessary in this direction before manufacturers like ourselves can hope to replace the greatly depleted stocks of accessories, and it will therefore be a matter of a few months before the

Mr. John Duffy

B.S.A.

MOTOR BICYCLES

TESTIMONY FROM FRANCE.

"The B.S.A., as you know, is standard in the French Aviation, which has many hundreds in use. I must say the poor machines have, on the whole, a very bad time and are driven very hard—the majority of their drivers had no previous motor cycling experience, are rather careless and 'fast'—everybody seems to ride them and to learn to drive on them, including officers—nearly always a sidecar is attached. Despite such drawbacks it is marvellous how the machines succeed in performing useful work in despatch riding, postal service, provisioning, and conveying passengers. One may say now that, before the B.S.A., all sorts of machines had been tried from small twins to big American Motor Cycles, and that under such handicaps they all failed to be of any real use.

"In conclusion, I feel I owe a debt of gratitude to the machine which has carried me so faithfully, through fair and through foul, for two years of war. She is still sound although a little disreputable looking, as you will judge from the enclosed photos."

Yours truly,

ROBERT SEXE,

Opinions.—

public can be sure of getting their favourite makes from the dealers' shelves.

Now a word as to prices. Labour is still costing more than double in pre-war times, and by a recent Act of Parliament the present rates must remain in force for the next six months, which fact means generally that, during the whole of this year, unless material gets much cheaper, which is not anticipated, present prices will more or less have to remain.

My advice, therefore, is that nothing is to be gained in delaying purchases in the hope of a speedy reduction in price; and in order to help to find work for munition workers, now that the majority of munitions contracts have been completed, and for the returned soldiers, it is a national duty to purchase what is really necessary.

From Mr. A. P. Young, Chief Magneto Engineer, British Thomson-Houston Co., Ltd.

AS I consider the future prospects in this country of the motor car, motor cycle, and other industries that depend on the use of a petrol motor, the predominant thought in my mind is that the development of these huge industries in the years that lie ahead will never again be solely dependent on high-tension magnetos manufactured in Germany. This striking transformation has been brought about by the greatest war in history, and it is not a very happy reflection—but nevertheless true—that it required an international upheaval of such magnitude to secure this tremendous result.

The British magneto industry is now a factor of vital importance, and it won its laurels during the war when the whole of its concentrated effort was applied to the development and construction of aeroplane magnetos of superlative quality for our Air Forces.

Mr. A. P. Young

The success that was achieved can be gauged by the single striking fact that when the Armistice was signed it was generally admitted by aircraft experts that the British Air Force in equipment and personnel was second to none.

Now that the war is all but ended the British magneto industry has with avidity turned its attention to the development and standardisation of all kinds of magnetos for motor cars, motor cycles, and other motor vehicles. The invaluable experience gained during the war in the design and construction of aeroplane magnetos will be reflected in the designs that will appear during 1919. From my knowledge of what has been and is now being done I can say that these magnetos will be better than the German product, and they should prove themselves superior both mechanically and electrically. I venture to predict that the experience of motorists on the road will confirm this view, which is based on an intimate knowledge of these contemporary designs.

From Mr. Alec S. Ross, Popular Clubman and Competitions Official.

WHEN our armies are finally demobilised, doubtless thousands of young men who, before the war, were satisfied with a town existence and a sedentary life will want something more vigorous, exciting, and manly.

Every one of these young men is a potential purchaser of a motor bicycle.

The yearly output of motor cycles in this country increased from about 6,000 in 1908 to something like 60,000 in 1914, but even now I am convinced that we are only on the fringe of the motor cycle movement. Factories must be enlarged and the output increased a hundredfold. Prices must come down eventually, but makers will be ill-advised if they sacrifice quality to low price. The ultra-cheap and shoddy machine will alienate many possible enthusiasts and do much harm to the industry and the sport. Low prices must be the result of improved methods of manufacture and large output.

From Mr. E. R. Troward, of Rider Troward and Co., the Hampstead Motor Cycle Dealers.

AS regards reconstruction as applied to motor cycle retailers, there is surely room for improvement and reform—more efficient service, better class second-hand goods, better over-guarantees.

Let us see that in setting our house in order we do not overlook the cleansing of the retail motor cycle trade. In pre-war days buying a second-hand motor vehicle was like buying a horse—one took an expert with one to avoid being "done." I know nothing about clothes, but I do not take a clothing expert with me when I go to my tailor for a new suit, nor do you take an expert with you when you go shopping at Selfridges or any of the big stores.

Therefore, let us see that the retail motor cycle dealer inspires confidence in his would-be purchasers, so that a novice may be able to buy anywhere without fear. The trade now has a very big future before it, and it is up to the trade to treat all customers well, and to give good workmanship and effectual guarantees, especially as regards second-hand goods, where guarantees now are mostly lacking.

Mr. Alec Ross.

Mr. E. R. Troward.

From Mr. Geo. Pettit, Proprietor of Maudes' Motor Mart.

AS an agent, the most sound advice I can give to a prospective motor cyclist is to buy now. As events are progressing, there appears little doubt but that the man who leaves his order until the sun shines will be left without a machine, new or second-hand.

During the year 1919 I think we shall see few startling models on offer, as most manufacturers are rightly keeping to the tried and trusted designs until they are free to supply something new which will, in, say, ten months' time, need every test to which a maker can subject a machine. But 1920 will be an eye-opener to every serious motor cyclist.

There will still be a few smaller manufacturers working on the old British principle of "individual output"—if I may use such an expression; and, provided these manufacturers turn their attention to a first-class product, their machines will still be in demand, since a number of buyers will always insist on some such special type of mount, even should the price be double that of a like machine manufactured on the quantity scale.

There is little doubt but that the motor cycle is coming into its own as the cheapest form of locomotion known in this country for either one or two persons.

From Mr. Harry Bax, of Godfreys, Ltd.

THE trade of a motor cycle agent necessitates dealing in second-hand machines. This second-hand business—with all its possibilities for sharp practices—is certainly open to improvement for the credit of the trade and the protection of purchasers of second-hand machines.

The buyer of a new machine relies on the guarantee of the maker; the purchaser of a second-hand machine on the guarantee of the agent—specific or implied. When, as in some cases, the value of this guarantee is limited to its advertising possibilities, the buyer suffers.

But the agent can, and should by actual examination of all working parts of every second-hand machine passing through his hands, make his guarantee of equal value to that of the manufacturer. He certainly cannot do it otherwise. In other words, it should be his business to reconstruct every second-hand machine so that his guarantee rests on a foundation of fact and not speculation.

That something should be done to make it less easy for the dishonest agent to exploit the novice, all who have the interests of the trade at heart will admit. How it is to be done is one of the problems of reconstruction.

A fourth selection will appear next week.

Mr. H. Bax

THE PRESSED STEEL FRAME.

A Midland Firm's Striking Departure.

All the plating, flanged for strength, is of stout gauge, the side plates being of lesser gauge than the top plates; the head is formed in a separate piece with side wings, to which the side plates are bolted.

The Engine Unit.

The engine unit is complete in itself—so complete, in fact, that when the chain and petrol pipe are disconnected and the baseplate unbolted, it can be entirely removed from the frame, carrying with it the two-speed gear box, magneto, silencer, and carburetter. No part of the engine unit is attached to the frame, yet so accessible is the engine that with the cover plate removed it is possible to make any adjustment, even to the removing of the outside flywheel.

The engine is of the four-stroke type and of 427 c.c. capacity, and is placed horizontally with side-by-side valves on top of the cylinder, but its general details we omit at present, as certain patents connected therewith are not yet completed. The same remark applies to the method of springing and adjusting the back wheel. That it follows car practice throughout and gives promise of excellent

results is the most we can say at the moment.

There are numerous other interesting details, which will be dealt with later. We hope to have a machine on test shortly, when our actual experiences on the road with this unique mount can be given. As it stands at present, it presents no particular difficulty; some faults may develop, but nothing which cannot be overcome. In this connection, the friendly criticism of readers of *The Motor Cycle* is invited.

The designer has been particularly careful to obviate any chance of side play or want of strength at the head, engine plates, and rear wheel. The machine will be suitable for riders of either sex without alteration, and will be an undoubted advance on the point of cleanliness. The engine is completely shielded from the rider, and an ample dashboard and leg shields can easily be fitted, rendering the machine as nearly weatherproof as possible.

On the point of cost, whilst the preliminary models will certainly cost more to produce than a tubular frame, the saving when large numbers are built will be considerable.

THE pressed steel motor cycle frame has long been regarded as an ultimate development, but until recently there has been no particular tendency in that direction, in spite of the many advantages which, theoretically, it presents. We have, however, foreseen that the war-time experience of several of our motor cycle manufacturers with engine plates for aeroplanes would influence motor cycle frame design. Therefore it is of especial interest to find the makers of the Diamond motor cycles, D.F.M. Engineering Co., Ltd., of Wolverhampton, well advanced in the production of the first models of a genuine tubeless frame constructed entirely of steel pressings. Before proceeding further, it is as well to state that this firm is not yet in a position to entertain any enquiries relating to this machine.

A glance at our illustration shows what a distinct departure it is from usual practice. The novelty is not merely confined to the frame, but the engine unit also is unique.

The frame consists of two side plates carried right through from the head, downwards, to form part of the engine carrier, and, upwards, over the back wheel, to form strengthening valances on the back mudguard. The two plates are connected behind the head by (1) a segmental plate covering the petrol tank, (2) by the tank itself when in position, (3) by a removable plate over the engine, and again (4) by the back mudguard. The whole is completely stiffened by the engine unit baseplate, which is bolted in from the under side.

The frame design of the new Diamond motor cycle. Pressed steel is entirely to supersede steel tubing in its construction.

A SIMPLE ADJUSTABLE PULLEY.

NOT many of the usual fittings on a belt-driven motor cycle are more useful than an adjustable pulley. Even in these days of variable gears an adjustable pulley fulfils a very useful purpose. In the case of the older type of three-speed hub gears the adjustable pulley is just as useful as in the case of the combined belt and chain-driven motor cycle. In both these cases it allows the rider on approaching a hilly country to lower the range of all three gears, and will enable him to climb any hill with practically any load, and when the hilly country is left the tourist can again raise his gears, and so continue his journey in comfort.

The adjustable pulley made by Messrs. A. and E. Lower, 668, Seven Sisters Road, Tottenham, London, N.15, is a very simple and easily fitted device. In the

Sectional view of the Lower adjustable pulley.

Lower's adjustable pulley (lightweight pattern)

case of the lightweight pulley, it consists of an inner flange having a boss on which there are two threads. The thread nearest to the inside flange is left-hand; upon this the outer flange screws, while on the extreme outside of the boss is a right-hand thread for the cap that locks the outer flange in whichever position the rider desires.

The larger size pulley is practically the same as the lightweight type, but in this case the boss is made of steel and screwed into the inner flange, so that in the event of either flange wearing or needing replacing this is easily accomplished.

The pulleys are manufactured in the following dimensions, 4in., 5in., 6in., and 7in., and they are also made for any size of belts and suitable for either side of the engine.

More than

60,000

M-L Magnetos have been supplied to Government Departments during the past three years — They have recently been made at the rate of over 800 per week.

M-L Magnetos have satisfied the most searching tests of Government experts, and have made a reputation for efficiency and reliability under the most stringent conditions. Quality Tells.

We shall shortly be in a position to begin regular deliveries of a complete range of M-L Magnetos for Motor Cycles from the lightest to the heaviest, and for any combination of cylinders.

The
M-L Magneto Synd., Ltd.,
Coventry.

In answering this advertisement it is desirable to mention "The Motor Cycle."

"The
World's Best
Motor
Cycle."

Sopwith

A.B.C. 1919 Policy

Mass production of 3 h.p. Model.

Detailed particulars and price of the A.B.C. will be published in a few weeks. When you see its principles of design you will realise that there are brains behind it and technical capacity far in advance of any other motor cycle engineering achievement.

The following are some of its leading constructional features:—

ENGINE—Air-cooled flat twin of 400 c.c. capacity, mounted athwart the frame. Mr Granville Bradshaw's unique experience with air-cooled aero engines has been employed to the fullest advantage in this remarkable motor cycle engine. Overhead type valves of the highest possible efficiency are fitted—improving fuel consumption by 10% and power by 15% over other inefficient types of valve mechanism. Again based on aero engine experience.

UNIT CONSTRUCTION—Engine, gear box, and clutch are one complete unit, and the whole demountable by simply releasing four bolts. The unit is self-lubricating.

SPRINGS—Leaf springing front and rear, with both springs in unison and correctly applied—giving perfect stability and high-grade car riding comfort.

GEAR BOX—The famous 4-speed gate-operated A.B.C. gear box as fitted to early war models.

LUBRICATION—Automatic lubrication on car lines. The only attention needed is to "fill up with oil once a month."

FRAME CONSTRUCTION—The secret "lightness in strength" has been applied to A.B.C. frame construction, being 30% lighter than previous practice, and at least 100% stronger with correspondingly greater resiliency and freedom from fatigue.

BRAKES—Self-adjusting mud-proof cone brakes in place of the inefficient contraptions common to the motor cycle.

KEYNOTE—

Design not Guesswork.

ENGINE EQUIPMENT.

MORE LESSONS OF THE PLEBISCITE.

Record of Readers' Votes on Various Items of Engine Specification.

IN last week's issue we dealt at length with the proportionate popularity of different types and sizes of engines. We are now able to go into details concerning other items of specification.

Space last week prevented our including in the long article on engines the result of the voting on such points as carburetters and magnetos. Considering that all cars have "automatic" carburetters, and that the single-lever control is very desirable from a simplicity standpoint, it is somewhat surprising to find that in both solo and sidecar classes the two-lever type is favoured by the majority. The voting on this point was as below:

	Solo.	Sidecar.
One-lever type carburetter	32.8%	41%
Two-lever type carburetter	67.2%	59%

From the foregoing it is apparent that the demand for the two-lever carburetter is more insistent from solo riders than from those who use sidecars. Since the solo rider usually is keen to obtain every ounce of power, this seems to signify that single-lever carburetters have not yet been generally proved to be so satisfactory as the two-lever type. On the other hand, the sidecar driver is more inclined to consider the advantages of a single-lever throttle control. It should be noted that included in the figures given for the single-lever are a large number of votes in favour of twist-grip control from riders of American machines, and that without these the figures would have been very much less.

Magneto Drive.

Despite the large numbers of machines on the road upon which the chain as the magneto drive is giving every satisfaction, gear-driven magnetos secured more votes in both classes than chain and shaft drive taken together. It is questionable whether a train of gears is the ideal transmission for the magneto. Every gear wheel has to be supported in two bushes, and the gears themselves tend to increase mechanical noises. In addition the cost is higher than a chain, and, in some cases, higher than shaft transmission. However, the gear-driven magneto is voted for by the majority, as will be seen below:

	Solo.	Sidecar.
Chain-driven magneto	34.1%	35.1%
Gear-driven magneto	54%	48.6%
Shaft-driven magneto	11.9%	16.3%

In considering the above figures, it is well to bear in mind that, as reported last week, the flat twin engine as a type scored 40% and 28% in solo and sidecar groups respectively. Most flat twins have gear-driven magnetos. As a matter of fact, only a minor proportion of the flat twin enthusiasts quoted chain and shaft transmissions for the magneto. Therefore, if

we take these figures into consideration, the gear-driven magneto on other types assumes a very different aspect.

Magneto Position.

The popularity of the flat twin also affects the voting in connection with magneto position, as the bulk of the forms specifying a central position are in the flat twin class. The respective popularity of the three positions is shown below:

	Solo.	Sidecar.
Before the engine	15.8%	12%
Behind the engine	44.7%	52.4%
Central	39.5%	35.6%

It will be noted that the proportion specifying a centrally-disposed magneto is less than the percentage of flat twins, in addition to which quite a large number of readers who voted for four-cylinder engines specified a central position for the magneto. This discrepancy is accounted for by the many flat twin adherents failing to register their choice in magneto position, no doubt assuming that an opposed twin must of necessity have the magneto between the cylinders. Others, however, apparently did not agree that the central is ideal, and specified a rear position, but without any comment as to the reasons thereof. There were also quite a number of readers who signified their preference for centrally placed magnetos on V twins, especially in the case of the 90° twin. Several, however, mentioned the central position for engines of 50° and 60°, but did not go further to state exactly how this could be done.

Lubrication.

On the point of lubrication readers are not so definitely in favour of any particular system. The greatest voting is in favour of the conventional hand pump and mechanical pump.

	Solo.	Sidecar.
Hand pump	26.4%	19.4%
Semi-automatic drip	19.1%	15.1%
Mechanical	23%	27.4%
Forced feed	14.6%	21%
Automatic	4.2%	6.3%
Throttle controlled	12%	10.8%
Petrol	0.7%	—

Quite a large proportion of readers specified combinations in which usually the hand pump was mentioned in addition to a mechanical or automatic system. The semi-automatic drip feed system evidently is not so popular with riders as it promised to be a few years ago. The low number of petrol advocates is due to the corresponding low number of forms giving the two-stroke engine as ideal.

Our next article on the plebiscite results will refer to gears and transmissions.

Times to Light Lamps.

GREENWICH TIME.

Jan. 16th	...	4.49 p.m.
" 18th	...	4.52 "
" 20th	...	4.55 "
" 22nd	...	4.58 "

A Thoroughbred.

A new make of single-cylinder motor cycle which, it is whispered, will aspire to fame as a track machine, has been born in an aeroplane factory.

Mass Production.

Mr. Hugh Gibson, the well-known Bradbury and Clyno competition rider, in this issue suggests amalgamations of large motor cycle manufacturing concerns with a view to increasing production.

The £150 Proposition.

Those of our readers who are protesting against the rise in price of the *de luxe* sidecar and "threaten" to buy a Ford will be interested to know that this car is now £250 f.o.r. Manchester.

Opinions.

A third series of Opinions from well-known motor cyclists appears in this issue, and includes some interesting comments by men prominent in the "second-hand" business, who are anxious that this branch of the industry be placed on a better footing.

Imports and Exports.

Despite the consummation of peace, the value of exported motor cycles and parts continues to drop; but, although the value of imported parts is less, the total value of machines imported during December, 1918 (in spite of the prohibition on imports), is greater than for the same period in 1917. The figures for December of both years are here given:

IMPORTS FOR DECEMBER.

	1918	1917
Machines	£130	£22
Parts, etc.	£361	£1,669
Total	£491	£1,691

EXPORTS FOR DECEMBER.

	1918	1917
Machines	£22,046	£62,591
Parts, etc.	£23,671	£33,316
Total	£45,717	£95,907

The imports of machines and parts for the twelve months to December 31st, 1918, amounted to £22,479, as against £106,126 in 1917 and £176,015 during 1916. It is interesting to compare these with the 1914 returns, which give £187,676 for value of imports and £1,168,799 for the exports.

Price of Petrol in New Zealand.

A cask of eight gallons of petrol in New Zealand costs 27s. 6d., compared with the pre-war price of 12s. 6d.

A Scandal.

The position regarding war-worn motor cycles is most unsatisfactory. In this issue we give a number of photographs of these machines at Kempton Park and a review of the situation at the present time.

A New Motor Fuel.

According to *Oil News*, a petrol substitute has been discovered in Washington which, it is claimed, has greater thermal efficiency than the best petrol, and can be produced at less than half the present price.

The substitute has a kerosene basis, and is the result of more than five months' experiments conducted by Major O. B. Zimmerman and Capt. E. C. Weisberger, of the Research and Development Divisions of the General Depot at Washington.

It is claimed that the new fuel is odourless, tasteless, and non-corrosive, leaves less carbon deposit than petrol, requires less air or oxygen for combustion, and develops greater horse-power. The ingredients are cheap, and can be readily obtained, while the process of manufacture is simple. The fuel has been successfully tested in motor cars, motor cycles, and other vehicles propelled by internal combustion engines in both cold and warm weather, and under sudden variations of load.

Special Features.

WASTAGE OF WAR.
ENGINE EQUIPMENT.
BUYERS' GUIDE.

Exit the Ministry of Munitions.

The Ministry of Munitions shortly will be known as the Ministry of Supply.

Pre-war Competition Awards

No doubt there are a large number of medals in the hands of club secretaries waiting to be claimed by motor cyclists who won them in the competitions of 1914. As a case in point, Mr. Weldon, secretary of the Nottingham and District M.C.C., is asking for the address of Flight-Commander W. D. Longton, who, before the war, was a successful competition rider. We would advise all readers who have such awards to their credit to apply for them from the club secretaries.

The Industrial Reconstruction Council.

The second lecture of the series arranged by the Industrial Reconstruction Council will be held in the Saddlers' Hall, Cheapside, E.C.2, on Wednesday, January 22nd. The chair will be taken at 4.30 by the Rt. Hon. Lord Balfour of Burleigh, K.T., and a lecture on "Industrial Reconstruction in Government Departments" will be delivered by His Honour Judge Edward Parry. Applications for tickets should be made to the Secretary, I.R.C., 2 and 4, Tudor Street, E.C.4.

In America many motor cyclists turn their outfit into a motor sledge during the long winter time. Runners are fitted to the front and sidecar wheels, and the driving wheel made non-skid by means of rope or chain.

Not a Hint.

"Ixion" wishes to convey his best thanks to "An Old Reader," who sent him a box of cigarettes anonymously.

The British Motor League.

We are informed that a meeting of the British Motor League will be held on Friday, the 17th inst., at the Pillar Hall, Cannon Street Hotel, at 2.30 p.m.

Motor Cycle Club for Swinton.

An effort is being made to form a motor cycle club in the Swinton district. Riders interested in the idea are asked to communicate with Mr. R. R. Garner, 254, Chorley Road, Swinton, Manchester, who is endeavouring to arrange an inaugural meeting.

Better Equipment.

There is a decided tendency among manufacturers to include better equipment in the specifications of their new models, and the policy of building down to a price appears to be entirely disappearing. Larger tyres and better saddles are almost general on machines which before the war were regarded as cheap lightweights.

The Central Committee of Employment.

The Central Committee for the Employment of Discharged Soldiers and Sailors was formed in 1915 to tackle the problem of finding employment for those men discharged from the Services who before the war were connected in any way with the motor industry. All those seeking work should write to the secretary, Mr. T. W. Loughborough, 83, Pall Mall, London, S.W.; who will put their names on the register, classified according to trade. A full list of men now seeking employment or information as to the work of the committee will be sent to anyone on application.

New Year Honours.

We notice the names of the following well-known motorists in the New Year Honours list:

Capt. W. O. Bentley, who in years gone by was a skilful performer on an Indian and won many hill-climbs, is now in the R.A.F., and has been awarded the M.B.E., Military Division. When war broke out he obtained a commission in the R.N.A.S., and distinguished himself by designing one of the most successful air-cooled aeroplane engines built during the war.

We notice that Lt. M. A. J. Orde, R.A.F., whose performances on a Rover were frequently recorded in pre-war competition days, and who was a prisoner of war in Germany for two years, has been promoted to the rank of Substantive Captain.

Capt. G. de Haviland, O.B.E., whose name, besides being associated with the early Blackburne motor bicycles, is well known in aviation circles, has been awarded the D.F.C.

Similar awards and honours have been granted to Acting-Maj. W. G. McMinnies, the well-known Triumph and Morgan rider, and Acting-Maj. Cyril Patteson, M.C., one of our most skilful and enthusiastic motor cyclists.

Capt. (Acting-Maj.) S. R. Axford has been awarded the O.B.E.

**THE DISPOSAL OF
ARMY MOTOR CYCLES.**

**Latest Developments up to
the time of going to press.**

Bargain hunters, whether private individuals, D.R.'s, dealers, or manufacturers, cannot purchase new or disused Army motor cycles at the present moment. The control is in the hands of the Surplus Government Property Disposal Board, 6, St. James's Square, London, S.W.1, and this body has temporarily suspended operations until a definite disposal scheme is formed. For the benefit of potential buyers who are looking with keen interest, not to say consternation, on the apparent muddle in the disposal of the nation's property, we intend each week to give in this column the latest information obtainable on the question. In last week's issue, and in the current number, the position up to date is very fully and clearly outlined.

New Rex Models.

Two new models will shortly be placed on the market by the old-established Rex Co. These will be a 4 h.p. single with three-speed gear and chain-cum-belt transmission, and an 8 h.p. twin sidecar with all-chain drive. Both models will embody several new features.

Eastern Counties Motor Club.

Mr. J. W. Percival, of 5, Ruby Road, Walthamstow, honorary secretary of the Eastern Counties Motor Club, will be pleased to hear from all old members at the earliest possible opportunity, in order that a meeting may be fixed to arrange the club's programme and fixtures for the coming season.

Bradbury Peace Models.

As we are about to go to press we have received advance particulars of the Bradbury Peace models. These will include a 2½ h.p. lightweight four-stroke single, with engine 74.5 x 80 mm. (350 c.c.), two-speed countershaft gear and clutch, chain-cum-belt transmission, which will be offered at £63. The 4 h.p. single and 6 h.p. twin similar to the pre-war models at £82 and £100 also will be catalogued.

The danger that despatch riders and drivers of motor transport faced did not always come from the German trenches, as is witnessed by the Douglas flywheel and ambulance lamp, both of which were riddled by machine gun fire from an aeroplane.

American Prices.

The price of the Henderson four-cylinder machine in America is £80, or with full electric equipment £90 12s. The Excelsior twin is approximately £70.

The Peace Model.

The 1919 A.J.S. sidecar is £142 16s. and not £152 16s. as quoted in our schedule of prices last week. This price includes 700 x 80 mm. heavy Dunlop tyres, spare wheel and tyre, sidecar screen, apron, and stand.

**More Army Motor Cycles Awaiting
Disposal.**

Kempton Park is not the only place where disused Army motor cycles are awaiting disposal. A correspondent states that there are many at Grove Park, near Bromley, but here, unlike those at Kempton, the majority are under cover.

Motorists and the New Parliament.

Prior to the Election, the Automobile Association and Motor Union wrote to every candidate asking if he would be prepared to support (a) a modern and up-to-date Motor Car Bill introduced directly circumstances permit into the House of Commons under recognised auspices; (b) the reconstruction of the roads upon lines adequate and suited to modern transport; (c) active measures to assure a sufficient supply of fuel for such transport at a reasonable price, and to encourage the production of home-produced fuel as an essential to national security and prosperity. The total number of replies received were 341, of which 276 expressed entire agreement.

The Motor Cycling Club.

As previously announced in these pages, the annual general meeting of the M.C.C. is to be held on Wednesday, January 29th, at 6.30 p.m., at the Prince of Wales's Room, Pagani's Restaurant, Great Portland Street, London, W.1.

We have received a letter from Lt. Southcomb May saying that, as the result of the publicity given to the fact that the club thought of engaging a paid secretary, numerous applications have been made for the post. The M.C.C. Committee, however, has decided to postpone its decision for the present so as to give the club's own members still Overseas a chance of applying. In the meantime, Mr. Southcomb May is carrying on in his old capacity as hon. secretary.

The 1919 Blackburne.

We are informed by Messrs. Burney and Blackburne, Ltd., Tongham, Surrey, that the illustration of the motor bicycle which accompanies the paragraph appearing in our issue of January 2nd is not really a correct representation of the latest 1919 Blackburne, but is rather a suggestion of "the ideal machine" conceived by Mr. J. H. Holroyd, the firm's works manager.

We hope very shortly to be in a position to give an extended description of the new model Blackburne, the latest of a type which made its reputation for reliability before the war. It is worthy of note that the Blackburne motor cycle was spoken of most favourably in Maj. Watson's excellent book, "The Adventures of a Despatch Rider."

LESSONS OF THE TRACK.

Racing and its Effect on Design.

ANY discussion on the effects of the knowledge gained by racing and speed work on the design of the touring machine is rendered difficult by the necessity of clearly defining the differences between causes and effects so as to produce convincing arguments. The facts that the results obtained are so decisive and yet so easily affected by human element show that a clear analysis of the various points at stake are open to misconstruction. Generally speaking, however, the results obtained in the majority of cases are identical for racing and touring, with the exception that they are much more magnified in the former.

Evolution by Track Tests.

Latterly a great deal more attention has been paid to comfort than to speed, but at the same time the leading minds have continued to develop their theories on the track, and all the important results have necessitated experiments beyond the capabilities of ordinary touring mounts. Since practically all the real development in engine design has centred on the four-stroke cycle, a number of types have been brought forward with more or less success, current work becoming merely a question of perfection in details. The lessons learned from each experiment conceived as a means of perfecting a machine have invariably been introduced into the pleasure vehicle, resulting not only in its development but in improved methods of manufacture.

Machines have been seen on Brooklands, for instance, with compression ratios as high as 5 to 1 without exhibiting signs of pre-ignition and overheating—quite contrary to theory. The value of this lies in the demonstration of the fact that higher compression ratios may advantageously be employed, given suitable valve and combustion chamber design, on touring mounts.

Weight reduction has also become of importance, and this demands the employment of the highest class of materials. In an effort to decrease connecting rod angularity so as to permit of longer strokes without any greater loss in transmitting the explosive force to the crank pin, very long connecting rods become necessary. Chrome-vanadium steel has been successfully used for these parts, stressed up to 60,000 lb. per square inch. Steel pistons turned to $\frac{1}{16}$ in. at the skirt have proved satisfactory in every respect. These two important factors are receiving marked attention from designers. As regards the valve-in-head cylinder design many of the racing limits can be adapted to the touring engine without any ill effects, the reason being that in no instance does ordinary use demand such strenuous service; the throttle is never wide open for any length of time, consequently the volumetric efficiency is seldom at its highest, and the explosion pressure is necessarily diminished. The same theory holds good in the lack of urgent need for such extremely high engine speeds, and this allows of heavier reciprocating parts as a means of reducing the cost, without any apparent falling off in power.

The many attempts to increase engine efficiency have forced upon us a marvellous increase in piston

speed, and remarkable results have been obtained that would doubtless never have entered the designer's head when considering stock production.

As an important factor bearing on the matter of engine speed, not only the details of cam design but also valve timing have come in for a generous share of attention, and while experiments along this line are fairly easy, the wonderful results are demonstrated only by the fast-moving vehicle.

Timing the opening of the exhaust as early as 70° ahead of dead centre, and the closing of the inlet valve as late as 63° past lower dead centre, with practically no attention being paid to the closing of the exhaust and the opening of the inlet valve, within reasonable limits, have been proved thoroughly practical and efficient in touring use, as well as in racing engines, and to racing alone I believe this development is due.

The Problem of Stresses.

Generally it may be stated that even in the midst of such examples of the modern designers' ability and the remarkable developments introduced by metallurgists, it has been surprising to note the new things to be learned at every race meeting. Prominent among these is the fact that so many undue stresses on the frames and engines seem to occur that cannot be calculated in any way, but are demonstrated plainly in a racing machine. This applies to all parts of the machine and illustrates fully that fatigue-resisting metals must be used practically throughout. Keys, holding gears that have pressed fits, and other minor parts such as small spindles and shafts that appear in ordinary carbon or nickel steels to be more than strong enough, considered from the standpoint of known stresses, will fracture frequently at varying periods. No doubt the same conditions prevail in touring mounts, but are often attributed to misuse or neglect, and occurring as they do at long intervals, the reasons are seldom sought and consequently the right conclusions never reached.

The Value of Track Work.

Although it may be that few actual designers personally participate in racing, the points that crop up, and are made public, in connection with track machines are found to be the subject of discussion by both trade man and amateur in almost every quarter, consequently, if the question be given fair and unbiased consideration, the statement that racing is directly responsible for the development of the modern motor cycle—which means that manufacturing facilities must keep pace with its progress—should be beyond contradiction.

MASCOT.

BROOKLANDS!

Track racing as an aid to the development of the motor cycle is discussed on the previous page.

NEW DATA REGARDING ENGINES.

Precis of Mr. L. H. Pomeroy's Recent Paper before the Institution of Automobile Engineers.

AN informative paper was read recently before the Institution of Automobile Engineers, by Mr. L. H. Pomeroy, dealing with the influence of valve area, revolution speed, and combustion chamber design upon horse-power and thermal efficiency. While the experiments which form the basis of this paper were of necessity conducted with large water-cooled, four-cylinder engines, the data obtained can be applied in no less degree to the smaller air-cooled engine of the motor cycle.

Experiments were carried out with two four-cylinder engines practically identical in design save in the arrangement of the valves, which were of the orthodox side by side type in one engine, and overhead in the other. These may for convenience sake be termed engine A and engine B.

The figures given by Mr. Pomeroy showed that in these engines the maximum b.h.p. obtained was largely independent of the gas velocity through the inlet valve, and that much higher gas velocities can be used than are common practice without adversely affecting the maximum b.h.p.

Engine B proved to be decidedly better in respect of m.e.p. than A, but in each case the calculated m.e.p. was fairly steady at the various inlet gas velocities,

and did not fall off appreciably, i.e., more than 5% for gas velocities up to 300 feet per second. It was also shown that the brake m.e.p.'s of the order of 95 lb. per square in. can be obtained with inlet gas velocities in the region of 300 feet per second.

The curves obtained showed that the consumption per b.h.p. rapidly falls with the increase in the inlet valve gas velocity, but rises again with a further increase in gas velocity as the upper limit of revolution speed is reached.

It is well known that turbulence is essential for both power and economy, but these tests indicated that in considering turbulence, inlet gas velocity must be regarded as to its relation to revolution speed or piston speed, and there is a certain minimum relation between the two which produces the necessary turbulence for approximately complete combustion at all speeds. The conclusions formed by Mr. Pomeroy in considering these results are:

- (1) That consumption is not directly related to inlet gas velocity.
- (2) That sufficient turbulence is developed to produce approximately complete and rapid combustion at quite low gas velocities.

- (3) That the improvement in consumption with increase of inlet gas velocity, shown by the curves, is related to revolution speed and not to gas velocity as such.

The general conclusion drawn from an examination of the results showed that the consumption of petrol per b.h.p. per hour is not materially affected by the inlet gas velocity in any prescribed number of r.p.m.

Mr. Pomeroy claimed that the chief advantage which might be expected in respect of the more compact combustion chamber in engine B is that the jacket loss during explosion and expansion would be less, and that part of this gain would be reflected in an increased m.e.p. The petrol consumption results, however, do not support this view, and show that, although the thermal efficiency increases with the speed, the actual consumptions are substantially the same in each engine at any given speed.

The principal lessons from the work done were, in the opinion of the author, the evidence of the high charging capacity of a small overhead inlet valve, and the comparative independence of consumption in respect of engine speed and torque for horse-powers up to fifty or sixty per cent. of the maximum.

CAMPAIGN

IT is vital to the Motoring Community that there shall be:

**STATE REGULATION OF PRICES OF ALL
MOTOR FUEL. STATE ENCOURAGEMENT OF
PRODUCTION OF MOTOR FUEL WHEREVER
POSSIBLE WITHIN THE EMPIRE.**

To obtain these advantages it is necessary :

- (a) *To press for immediate State action.*
- (b) *To obtain standard specifications for home-produced Motor Fuels.*
- (c) *To encourage production at home or within the Empire of industrial alcohol as a constituent Motor Fuel.*
- (d) *To combat, and obtain State assistance in preventing the danger of home-produced Fuels being manipulated or controlled by any Trust.*
- (e) *To obtain State prohibition of exports of home-produced Fuel except supplies surplus to national needs.*

CUT HERE

To the Secretary,

The Automobile Association and Motor Union,
Fannum House, Whitcomb Street, W.C.2.

*I undertake, as far as may be in my power, to assist in the
conduct of the Motor Fuels Campaign as outlined above.*

Your
Motor-cycle
—and Dunhills

It is all very well to picture that whirl through the countryside as one long spell of unbroken pleasure, but it is more practical to reflect on the possibilities of mishap and to anticipate the troubles that may arise. It is still more practical to arm yourself with all those "Motorities" which add to the joy and enable you to deal promptly and effectively with "troubles." It is not good to find yourself in difficulty just as the shades of night are falling and you at a spot "miles from anywhere." Be a "road-wise" motorist and equip yourself fully and efficiently at Dunhills.

Write, call or 'phone for the booklet "Dunhill's Motorities for Motor Cyclists"—there's nothing you need it doesn't contain.

The Latest Royal Ruby Productions.

The Military Model with Additional Refinements.

THE Royal Ruby Cycle Co., of Manchester, have been engaged, like other motor cycle manufacturers, on munitions of war for the past two years or more, to the partial exclusion of their proper line of work. The transition of their new peace time programme is rapidly taking place, and regular production will shortly be assured.

The small two-stroke, well known in pre-war days, will continue to be produced as before. The larger model for heavy sidecar work will be a refined development of the military model, originally designed for use in Russia.

Substantial construction is its outstanding feature, and there are numerous special points in the design, including the eccen-

(Left) Sidecar lugs at the head of frame. Note the cross projections which take shearing stresses. (Centre) The rear brake with parallel action. (Right) Method of padlocking the stand to prevent theft.

tric movement provided to slide the gear box when making adjustments. Others are the triple front down tube; the interesting silencing arrangement; the safety stay strengthening the gear box bracket and seat-pillar tube; the ample carrier and easy method of completely removing it with the mudguard; adjustable footboards; large under shields and side shields; and parallel action for the rear brake. All these details are fairly well known. Among the later refine-

ments are the total enclosing of the chain drive, special design in sidecar lugs to avoid throwing the shearing stress on the bolts, and a neat addition to the rear stand whereby it can be padlocked in position to prevent the machine from being stolen.

Attractively Finished.

The Sturmey-Archer gear is to be embodied in future models. The familiar War Office drab green finish of the Russian models has been discontinued, and a more handsome appearance produced in black and red with gold lines. A spring frame model is in course of preparation, and extremely satisfactory results are being

The latest 8 h.p. Royal Ruby sidecar combination with totally enclosed drive and Sturmey-Archer three-speed gear.

A neat method of attaching leaf springs to the sidecar chassis.

obtained from the experimental machines. No doubt this model will shortly find a regular place in the firm's programme.

We illustrate a new means of fixing the leaf springs to the sidecar chassis—a marked improvement on the usual U bolts.

Altogether the machine is a substantial and thoughtfully designed model.

FURTHER DETAILS OF THE 1919 AMERICAN HENDERSON.

FURTHER details of the latest pattern four-cylinder Model Z2 Henderson motor bicycle are now to hand from the British agents, Messrs. Robertson's Motors, Ltd., 157b, Great Portland Street, London, W.1. Some preliminary notes concerning this machine were given in the issue of October 17th last year.

The cylinder dimensions are given as 70 mm. x 76 mm., totalling 1,168 c.c. The steel pistons are very light, having two piston rings, split bronze small end bushes lined with babbitt, and hollow gudgeon pins. The crankshaft is a one-piece drop forging with two end and one centre bearing. The valves are drop forgings of alloy steel, light and

very tough. The tappets are adjustable, the valve stems and tappets being provided with light dust-tight covers to eliminate noise. Both the crankshaft and big end bearings are split bronze, and babbitt lined.

The engine has been increased in size; it is better balanced, and will run more slowly than previous models.

The lubrication is effected by means of a worm-driven oil pump, which supplies the lubricant to a large sump in the crank case, from which it is fed by splash through grooves and channels to all the working parts. To supply the engine with extra oil, an emergency auxiliary hand pump is fitted.

The three-speed box, which is integral with the crank case, has 4½, 7½, and 10½ to 1 ratios, which last-mentioned ratio should be low enough to enable the machine to climb any hill in the United Kingdom, when the power of the engine is taken into consideration.

The change speed lever, situated on the left-hand side of the tank, is provided with a locking device which prevents the gear from being changed till the clutch is disengaged. The kick starter is fitted directly to the gear box layshaft, and one stroke turns the engine over two compressions.

The tanks will hold two gallons of petrol and two quarts of oil.

LETTERS TO

THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Herford Street, Coventry, and must be accompanied by the writer's name and address.

LUBRICATION.

Sir,—Having read so much of late of the different systems of lubricating motor cycle engines and the different oil pumps designed for them, may I ask why more use is not made of the geared oil pump? In my estimation, it would be ideal. It would start and stop with the engine, which is just what is required, and a very small cylinder could be fitted on the pipe or oil way line, fitted with a plunger, say $\frac{3}{16}$ in. in diameter, which would come up above the top of cylinder about $\frac{1}{4}$ in. One could then tell if the pump were working.

I should like to know what readers of your valuable paper think about this.

H. WRIGHT.

A LONG STROKE TWO-STROKE.

Sir,—I have been waiting twenty years for a $3\frac{1}{2}$ h.p. long stroke, two-stroke engine. Is it ever coming along? I hate wearing valve guides, grinding in valves, adjusting them, chattering valve gears, etc. It seems to me that a very long cylinder has greater cooling opportunities, greater suction for gas, and the sweetness of running equals the flat twin. What is mechanically wrong with such an engine? Do you think I shall chance to see one before my three-score years and ten? (I am only fifty.) I should so much like to ride such a machine before I die. I want also very much to know what is against 12 in. mudguards? I do so hate to put my manicured hand up a tight-fitting valance to remove mud when the frost lifts; it makes me feel quite naughty. I also want two and a half gallon tanks and adjustable handle-bars, but the trade conspires against me.

R. R. RICHARDSON.

THE THREE-JET BINKS CARBURETTER.

Sir,—As the originator of the controversy anent the "dead spot" in the three-jet Binks carburetter, I would like to point out that my conclusions were not jumped at as the result of a single test on one machine. I believe I used my first Binks instrument in the summer of 1911, and I have been using it consistently ever since on every type of machine from 2 h.p. to 8-10 h.p. twins. In all machines—they number thirty-seven to date, this "dead spot" has been a marked feature, only varying slightly according to the type of engine. Twins and two-strokes, with their more even induction impulses, did not show it so markedly.

I can quite understand that a four-cylinder engine would not show this bad feature very noticeably, but I do not think that my contention can be controverted by the result of a test on one machine. The fact remains that numbers of users of this instrument find this fault with it.

H. LINDSAY, M.B., CAPT. R.A.F.

LEAKAGE OF MAGNETISM.

Sir,—I have read with interest Mr. Wm. Alexander's letter in your issue for December 5th *re* leakage of magnetism.

It seems a pity that an otherwise good magneto should be spoilt by this trouble, when the remedy is simple, and the trouble can be cured as mentioned, or, better still, by a steel sprocket which has a brass centre, this being fixed to the magneto shafts.

In conclusion, it is extraordinary that the fault has never been rectified by the makers. Were it eliminated the Dixie would not only be a simple, but at the same time a good magneto.

J. P. J. CHAPMAN.

Sir,—When I first wrote you *re* leakage of magnetism, I knew I should have a good deal of criticism on this point.

Now to answer "Sgt. 274 (M.T.) Co." Admittedly the magnetism does not "alternate"; it could not do so. My

meaning was, it passes through the rotor and the laminated field alternately. I have fully taken into consideration the position of magnets compared with other types.

Thirdly, that I have not located its peculiarity, I beg to differ, for it is curious that a brass sprocket cured it. It is also possible that a thousand magnets can be correct and the 1001st be wrong. Concerning other makes of rotating pole magnetos, I am not conversant with them.

I think this alone answers Mr. M. Clayton's letter, except for the condenser. I have not had trouble with this. It was not only examined, but my machine is in a centrally heated garage. Finally, my deductions have been drawn from my personal experience with and without a non-conducting sprocket wheel.

J. M. CHAPMAN.

THE FUTURE OF SURPLUS GOVERNMENT MACHINES.

Sir,—Having read the article by your contributor "Cantab" on "The Future of Surplus Government Machines" in *The Motor Cycle*, of January 9th, I should like to express my agreement with his conclusions.

Having seen the motor cycles, exposed as they are on Kempton Park racecourse, I am firmly of the opinion that no one except the makers of the various machines themselves could ever get them in proper riding order and satisfactory condition. Any speculator might buy 100 of these machines in the hope of completing seventy-five, but it would be a pure gamble. The seventy-five would even then not be likely to add to the reputation of their respective makers. Seeing all these machines are national property, it is in the national interest they should be put in sound condition by the makers for the Government at controlled profits, and offered to the motoring public by the makers, through agents, or otherwise, as a sound investment for any purchaser.

H. HASKINS.

ENGINE CAPACITY.

Sir,—The analysed census of readers' opinions upon the question of desirable cubic capacity is interesting, but in some respects a little misleading.

For one thing, it was not the average man in the street who sent in the bulk of the voting papers, but the enthusiast, whose tastes would generally sacrifice lightness to speed and power, even to an excess of the latter.

As a proof of this, if this voting were a final criterion, the sale of ultra-lightweights is finished, whereas we all know differently. Certainly the little machines have their faults, but there is a much larger proportion of people who will buy them than the voting indicates.

For another point, those who have voted so heavily for a 500 flat twin, or against a 350 to 400 c.c., are not exactly influenced by a desire for a big cylinder capacity, regarded from its point of size, but by a desire for the power that they expect to get from a 500 flat twin, as compared with the power that they expect to get from a 350 or 400 flat twin.

If any machine can give those voters that measure of power hitherto needing a 500, but give it from cylinders only measuring 400, and with corresponding decrease in weight, then it is safe to assert that the same riders would have voted for the 400 in preference.

Ergo, let us hope that the makers of the 350 and 400 machines will not be influenced by the statistics to drop their 350 and 400 models, but, instead, to develop the power of the 350-400 till it satisfies sporting riders more than did the pre-war models of that size. For the average tourist, the motoring equivalent of the "man in the street," the 350 c.c. mount was in 1914, and still is in 1919, as great a favourite as the 500 c.c.

FRANK WHITWORTH.

An Apology

To the thousand and more
readers of "The Motor Cycle"

who have written us concerning the

PREMIER

SUPER RUNABOUT

We wish to express our regret that we have been unable to send them the advance list for which they have asked.

The abnormal conditions prevailing at the present time are responsible alike for the printer's delay in delivering the list and our inability to cope with the correspondence.

Immediately the list is off the press the same will be forwarded. In the meantime, we invite others who are interested in a clean and efficient passenger machine to send their names and addresses

The Gap

in knowledge of
motor cycle construction

"The World's
Best Motor Cycle."

Copyright.

Has the gap between 1914 and 1919 been stored with fresh knowledge of motor cycle construction? Are 1914 designs to be revived in 1919 with just detailed improvements?

We have stored the 1914-1919 gap full with motor engineering knowledge, and motor cyclists will have the full benefit of it in the A.B.C.

The 1914 standard of design is past history. The 1919 A.B.C. will make history. All the knowledge and unique experience gained in producing the A.B.C. aero engine—the world's masterpiece—are being used in designing the A.B.C. motor cycle.

The design of the whole machine has been worked out—not guessed out—as will be seen when the A.B.C. Catalogue is issued.

OVERSEAS MODELS.

Sir,—All we Colonials are indebted to you for your efforts to bring home to English manufacturers the need of meeting Colonial demands. I expect to be home shortly on leave, and shall be on the look out for a combination that will meet local requirements. Failing satisfaction, I shall return here and invest in another Yank. But I hope this will not be necessary, for we all want British machines, if only the British manufacturers will give us the right sort of goods. Ceylon.

(REV.) A. M. WALMSLEY.

TANGENTS OF OBSERVATION.

Sir,—With reference to the discussion in your paper *re* tangents of observation, I have noted the remarks of Mr. Holland and "Curious," and I enclose the following formula, which I think fulfils their requirements on the distances at which objects can be seen, according to their respective elevations and the elevation of the eye of the observer, from sea level:

$$D = 1.42 \sqrt{H}.$$

It can be seen by this that an object 20ft. high is visible to an observer whose eye is 300ft. above water from a distance of 30.88 miles, arrived at thus:

	Distance visible.
20ft. elevation	6.34 miles
300ft. "	24.54 "
	30.88 miles

Which I think somewhat upsets the idea of seeing 200 miles from anywhere with the naked eye.

Egypt.

GUNNER HARLE.

GUDGEON PIN FIXING.

Sir,—I was much interested in "Ixion's" remarks on December 26th, 1918, *re* lubrication. He says: "If he keep the excess of oil out of the cylinder, the gudgeon pin bush may complain." Then again: "When the oil supply to the cylinder is reduced to rational proportions, our tiny gudgeon pin bushes will be overheated and overloaded, unless they are redesigned in the meantime."

Now, why in the name of everything wonderful, do not our engine designers take a leaf out of Mr. Ford's book, and construct their gudgeon pins on his well-known and tried principle? There we have our gudgeon pin made a fixture to the connecting rod, and a bronze bush pressed in the boss on both sides of the piston. Thus there is double bearing surface which gets ample lubrication from the cylinder walls. Another great feature in the above design is the elimination of any gudgeon pin fixing trouble.

I hope to hear other readers' opinions on this important, though much neglected, matter.

R. DE B. KENNARD.

THE IDEAL SIDECAR MACHINE.

Sir,—In the sketch published in *The Motor Cycle* for January 2nd, page 13, I note that the designer has placed the magneto in the correct position! Such a thing, I think, has never been done before. In all machines that I have examined, or ridden, the magneto is either placed in front of the engine, right over the exhaust box, where it gets dangerously hot and cannot be lubricated, or it is placed behind the engine, but wrong way round, so that the contact breaker is towards the sidecar, and so cannot be adjusted without detaching the sidecar.

The only proper position for a magneto is behind the engine on a platform insulated with thick fibre or asbestos board, so that heat cannot be conveyed from the engine, and the magneto must be driven from the left-hand side of the engine (as shown in the sketch referred to), so that the contact breaker is on the right-hand side of the machine, and can be got at without interfering with the sidecar. Why so many (I think all) manufacturers make the mistake of placing the magneto in either the first two positions referred to I cannot imagine.

I have at present a machine with the magneto in front of the engine. The bearings are packed with vaseline which is supposed to last for 4,000 or 5,000 miles or more, but after packing the bearings I have examined them after a few days and found that, owing to the high temperature conveyed from the exhaust box, every trace of vaseline had disappeared, and they were practically running dry! Every designer should know that vaseline (or other grease) becomes liquid

at a temperature of 200° or less, and so the magneto should be placed, as I suggested, behind the engine on an insulated plate.

Also, the low position (when in front of the engine) is all right if a pit is available; otherwise it is not pleasant to have to "grovel in the dust" when attempting to adjust the contact breaker, and it is also rather a nuisance to have to dig a pit beside the machine if a breakdown occurs on the road! Owing to the method of "securing" the magneto sprocket generally adopted—a taper spindle only; no key or other positive fixing—these breakdowns are by no means infrequent, as I know from bitter experience in the past.

M. HITCHCOCK.

[Naturally the magneto will get hot if placed immediately above the exhaust box, but this is the first complaint we have received of such serious consequences, and this trouble does not necessarily exist in all motor cycles having the magneto in a forward position.—ED.]

SPRING FRAMES.

Sir,—I venture to suggest a design of spring frame, as shown in rough sketch herewith. This, I claim, possesses all the advantages of those which you have illustrated

A suggested design for a spring frame sent in by "H."

from time to time without their many drawbacks. The detail, while it may appear complicated, is not so when gone into. You will note the design embodies a leaf spring. East Dulwich, S.E.22. H.

POST-WAR MOTOR CYCLES?

Sir,—At last the veil has slightly lifted, and some manufacturers have the temerity to state boldly that they have actually a post-war motor cycle, or, if not, at least one designed, priced, and catalogued. Good. But, unfortunately, there are others. Let us be patient! We gave up our precious motor cycles in 1914, and after four years' abstinence our fingers itch to open the throttle again and travel the open road. But the time is not yet. Patience, only a few months more and your wish shall be fulfilled. Close your eyes to the attractive specifications and real prices which appear side by side our exhortations, and if you wait long enough you may find we are producing just the machine you want—or do not want!

Why, in the name of goodness, are some manufacturers so mystifying? They have a waiting list. Have they a policy, and, if so, why not disclose it? Surely, it would appear as if the dark hand of the Censor were at work. Is it that some firm is producing a wonderful engine, with which it intends to dazzle the world when we have all bought our choice? I was speaking to a manufacturer just before hostilities ceased and told him I was out to buy—would he favour me with some idea of his post-war motor cycle? "Ah!" he replied with a merry wag of his finger. "And the price, too?" I enquired. "Ah, ah!" he evaded again. I saw his advertisement last week inviting me to enter his waiting list parlour. Not I. If in two months there is only a waiting list, in how many months will there be a production of motor cycles?

The whole thing is preposterous. One knows the difficulties of changing over, but at least let there be plans made, catalogues printed, and prices fixed, especially by those firms who have been supplying motor cycles to the Government during the war. In the first place there was naturally some reluctance to specify prices; but, manufacturers, do not be afraid, show your hands; we know the worst, and have stiffened our backs. The last penny of my gratuity shall be yours, if you will only disclose the wonder you are producing in the dim, distant future.

APEX.

Ripon.

A CURIOUS CASE.

Sir,—As a long-standing reader of your excellent and always interesting paper, I venture to relate an experience of mine with an A.B.C. flat twin fitted with Dixie magneto. It has to do with the question of even firing and normal running with carbon high-tension brushes removed.

I (like one of your readers, "D.R.," from Mesopotamia, who writes in your number of November 21st) found that the machine, minus a brush, fixed evenly, but I did not even leave in the spring holder! I have tried several A.B.C.'s with both or one complete carbon brush removed, and could tell no difference either in starting or on the road. The gap from brass liner in vulcanite holder to the high-tension slip ring of magneto I measured just under $\frac{7}{16}$ in. to $\frac{1}{2}$ in.

How can one account for this, as there is nothing that one can think of which would induce the high-tension current into the holder and from there across the plug gap?

Mansûra, Egypt.

F. A. COWAN.

RACING TRACKS.

Sir,—I should like to endorse the suggestions put forward by Mr. W. Cooper in his open letter to the trade, published in the issue of January 2nd.

Before the war I was constantly advocating the construction of tracks in the North and Midlands, but at that time the idea did not seem to appeal to the majority of the manufacturers. One hopes that the generally broader outlook produced by the events of the last four years will result in the adoption by the industry of a less parsimonious policy in the matter of tracks, and of racing and competitions generally.

At the same time I cannot follow Mr. Cooper in his criticisms of Brooklands. Of course, the track is not quite ideal—in more than one respect—but it has nevertheless amply proved its value. Its renovation should be the first job of reconstruction, and it would be interesting to know what preparations, if any, are being made in this direction. Perhaps the B.A.R.C. will make a statement.

L. FRANCIS JONES, CAPT., R.A.F.

STRAIGHT TUBE FRAMES.

Sir,—*Re* Mr. Bradshaw's comments on the above subject, surely with regard to the lateral stresses a straight tube non-duplicate frame, triangulated for all stresses in a vertical plane, is on a par with a curved tube frame, in that it is flexible to those lateral stresses, so that it should not prove any weaker in that respect than a curved tube frame. The difference in the lengths of the tubes in the respective cases would be infinitesimal, so that the lateral rigidity would be approximately the same.

I cannot see, therefore, how lateral stresses can be used as an argument against using the principle in a vertical plane. As to my reference that proper triangulation has been demonstrated to be feasible in these pages, I regret that I cannot refer to the actual articles or diagrams, as, owing to having been on Active Service the last three years it has been impossible to keep back numbers.

However, I remember one diagram of perfect triangulation in a vertical plane, and also in any lateral plane, except for the forks housing the rear wheel, which could be braced girder fashion. All the tubes were straight and in duplicate, including those on top and below the tank, and there was an extra pair which braced the lower part of the frame, crossing each other, not parallel, dividing it into two triangles. It would, however, be rather difficult to house a tank sufficiently low in this frame.

So to embody the principle for quantity production a pressed steel tank forming the upper frame member (somewhat *à la* Premier two-stroke) would appear the best solution. Possibly this could be pressed in two halves. Each side could be arranged to be symmetrical, so that the same pattern would suit either side. And these halves could be welded together on the top and bottom edges, enabling the bottom of the tank to be pendulous, below the line of the bottom of the steering head. Duplicate tubes could depend from lugs on each side of the tank fore and aft, one pair from the head and two pairs from the saddle end to form two rigid triangles.

A small horizontal twin placed transversely would be housed conveniently at the fore apex, the rear apex being the centre of the countershaft. The rear end of the tank would possibly house integrally a cylinder containing a plunger and spring

for the spring frame, *à la* Flying Merkel. This latter arrangement has the advantage of absorbing part of the road shock by a horizontal component instead of all vertical. The centre pair of bracing struts from engine to saddle might be arranged to cross each other to give lateral rigidity.

However, no one can deny that Mr. Bradshaw's curved tube frame must promise a longer life than many straight tube frames on the market, ladies' models particularly.

R. M. WIGG.

WAR-TIME MOUNTS.

Sir,—It may be of general interest to your readers as well as profitable, if a correspondence is opened on mounts used during the war by the limited number of civilian riders with petrol permits.

Of course, every reader has marvelled at the superb reliability of military motor cycles (to say nothing of the equally superb dash and hardihood of their riders), as described in your pages from time to time. We Anno Dominis, C3's, and indispensables remove our hats and tender the hero riders our sincere gratitude, with an expression of admiration for the fine machines they have so capably handled.

During the four years of war I have had to cover many thousands of miles in a business-capacity, and, like every other civilian rider, have managed to "carry on" only under the greatest difficulties. Shortage of petrol and oil, difficulty of obtaining spares and of getting repairs done have given perplexity.

I have bought and ridden four machines during the four years.

First, I bought a two-stroke which did me well as a solo bicycle, but I wanted a machine to take a sidecar for the purpose of carrying goods.

I tried a $3\frac{1}{2}$ h.p. with hub gears. This made an excellent solo machine, its flexibility making a strong appeal after a "neck-or-nothing" two-stroke; but with the coach-built sidecar I attached to it I could never trust the gears. I always managed to change sweetly enough, but when tackling a stiff gradient with a full load I always got the impression, in changing down, that I was setting a David against a Goliath. So I sold it as a solo machine, and as a solo machine it is still doing well.

I next tried a $3\frac{1}{2}$ h.p. countershaft combination. The bicycle was heavy after the hub-gear machine. The chain-cum-belt transmission, however, gave a silky, reliable drive, the gears were delightful to handle, and one felt a robust confidence in tackling hills. As a double-purpose machine it was excellent, but in the end I found it too slow on hills and the engine liable to overheat in hot weather when the sidecar was loaded.

I next tried a 5-6 h.p. Rudge-Multi, which just filled the bill. The power it can be made to exert from its long cylinder is something to astonish those who do not know this type, and the way it climbs hills which cannot be rushed without knocking is good to experience. Its accessibility also makes one independent of the repair depot for all the ordinary purposes of cleaning out, changing tyres, grinding in valves, etc.—not that I do much tinkering; it never seems to require it.

I wore out two belts rather quickly, but I was buying experience. I now change down at the bottom of the hill to the gear I know will take me to the top, throttling down as I do so. My present belt has been running eighteen months, and looks good for another eighteen. It is a John Bull $1\frac{1}{2}$ in.

Starting up in winter was at one time no small operation, but I have acquired just the knack, and can always get away with three turns of the pedals.

The Control of Aeroplane Engines.

The Pilot's Work: Notes on Management.

By TORQUE.

An article on the same subject appeared on December 26th.

ON most engines lubrication is by pressure, recorded on a gauge in lb. per square inch. The correct pressure may be as low as 20 lb., or as high as 100 lb., according to design. In either case an excessive pressure is certain to be registered on first starting. The cold oil will build up heavy resistances in the small bore pipes, and the gauge will perhaps read 10 lb. or 20 lb. more than the standard pressure; nevertheless, in the more remote parts of the circuit (e.g., the far end of an overhead camshaft) the oil is not really circulating at all. So the engine is run at 350-600 r.p.m. until the gauge records the proper pressure. Too low pressure signifies a leak. Absence of pressure shows that the pump is out of action. Excessive pressure indicates resistance in the oilways, i.e., cold oil or dirt. When the pressure steadies at the correct figure, the engine may be gently accelerated.

The warming up of a big engine in winter may be a lengthy business, as the oil tank may contain many gallons of oil, all of which has to be warmed, as it requires to be circulated incessantly. When time is a consideration, the tank will be replenished with warm oil just before starting up. Even if this dodge is adopted, the oil in the more remote leads of the engine may not have begun to circulate when the engine has been running for several minutes. As the bearings are under load the whole time, it is best to switch off after three or four minutes' running, and wait a few minutes whilst the heat from the combustion chambers is conducted to cooler parts of the engine. The engine is then restarted, and run for another three minute spell, and so on, until all the oil in the engine and in the tank is hot. An alternative wrinkle consists of pouring a pint of hot oil into the cam case—usually the last detail to warm up: a plug is sometimes provided for this purpose, or the lid over one of the cam case compartments can be removed. The same dodge is employed with new engines taken out of store, and with engines which have been standing idle for several weeks.

The Tachometer.

The revolution counter now becomes the centre of interest. An aero engine is handled under very strict regulations with regard to r.p.m. Three separate limits may possibly be specified for a given engine. For example, at ground level 1,500 r.p.m. must not be exceeded. Above 10,000 feet the "normal" r.p.m. may be 1,600 r.p.m. and the "maximum" 1,700 r.p.m. These figures require some explanation. Some

engines are designed with such high compression ratios that it would not be safe to run them all out with a full charge of gas at ground level. At altitude the charge is weakened, and the engine may be speeded up. "Normal" represents the speed at which the engine may be run continuously; "maximum" is the absolute limit, and may only be maintained for a very few minutes; the load on the bearings may be *doubled* by accelerating from 1,600 r.p.m. to 1,700 r.p.m., and the bearings can only stand the maximum load during a brief spurt.

As soon as acceleration becomes safe, the pilot ascertains that the engine has been properly tuned and will give the maximum r.p.m. permissible on the ground, with the throttle in the appropriate position: in the engine described above, this will not be fully open. The aeroplane is meantime secured by chocks before the wheels and by men at the tail. We next proceed to test the ignition and carburation. The former implies running the engine up and down its range on each ignition separately: the latter demands rather more violent acceleration and deceleration, such as might be needed in a fight. A glance at the exhaust will indicate whether the mixture is approximately correct, and also whether the supply of oil is accurate: the exhaust should smoke a little at the first acceleration, and clear almost immediately.

The altitude control should be tested before taking off, but this duty should be reserved for specially competent persons, as it is a task of great delicacy and some danger. Opening the control weakens the mixture. A weak mixture burns slowly. If the mixture is unduly weakened at ground level, it will certainly burn and warp the valves, and may even flame down the inlet valve and cause a conflagration.

The "percentage" of control is known to the tester. He will accelerate the engine to its full "ground level revs.," and suddenly open the control. If all is in order, an instant drop of perhaps 250 r.p.m. should be registered on the tachometer. He just gives the needle time to steady, notes the reading, and slams the control shut again, before the valves can be damaged or a fire be caused.

Getting Off.

When absolutely satisfied that the engine is running perfectly in every respect, the pilot prepares to get away. The engine will be opened out gradually during the run up. After getting off, the tachometer may be referred to if the pilot is not completely at home with that particular type of machine. In taking off, the

The Control of Aeroplane Engines.—

chief possibility of a mistake lies in climbing too steeply. The pilot will know what air speed should be maintained, and this air speed is, of course, connected to some extent with r.p.m.

Gaining Height.

Unless a defect should develop in the engine, the pilot is now chiefly concerned with keeping his engine cool and economising fuel. If the machine is climbed too hard the water may boil, in which case a short dive or a horizontal cruise will be necessary to cool the radiator; nobody can afford to lose water at the commencement of a flight. Fuel economy is attained by careful attention to the altitude correction of the carburetter. This is not sufficiently sensitive to affect the power perceptibly at low altitudes, but it can nevertheless vary the fuel consumption, which is important, especially on four-engined machines which devour perhaps eighty gallons per hour. Consequently the pilot should set the altitude corrector with the aid of the tachometer as he climbs. With such a machine as the five-engined Gotha, carelessness with the mixture to the extent of a 10% error on the rich side in a six-hour flight would mean wasting sixty gallons of petrol. The "tankage" would have to be excessive to allow for such clumsy pilotage, and would reduce the bomb load by three or four cwt. Alternatively, if the tankage were kept down to the theoretic minimum, a bad pilot would not return from a long flight. On a Transatlantic flight the vital effects of perfect mixture are even more important. On rotary engines the mixture is controlled by a "fine adjustment" needle valve, the carburetter having no float feed. With one of these engines a careless pilot may register a consumption 25% greater than the normal. As rotary engines were chiefly used on fighting scouts with a three-hour "tankage," the bad pilot reduced every flight by a period of forty-five minutes.

Coming Down.

Horizontal flight presents no special problems in engine management, except so far as the use of the radiator screening device is concerned, and the neces-

sary setting of the altitude correction. Coming down is, however, quite a tricky business under certain conditions. In descents from a great altitude an accidental engine stoppage ("losing the prop."), due to choking on minimum throttle, is of small account, as the propeller is turned by friction with the air, and will restart a responsive engine in a dive of a few hundred feet. On the other hand, the engine is not necessarily responsive, when once the prop. is lost. The sparking plugs may oil up. The petrol level in the carburetter is greatly affected in a steep dive; and, unless the "flooded" petrol is evacuated by suitable drains, the excessively rich mixture may obstruct a re-start. Again, the radiator may freeze in a prolonged dive, or the oil may congeal very thoroughly. Some machines can safely be dived at 200 m.p.h., and in winter such a speed rapidly chills an engine. In all these respects both the engine and the aeroplane require knowing. Two engines of the same make may be equipped with different makes of carburetter, which require alternative handling in a descent. The temperature of the atmosphere varies daily. Different types of aeroplane furnish varying degrees of protection for their engines, so that a given make of engine may ask for one type of humouring in a Martinsyde, and another sort of coaxing in a D.H. On some machines the throttle "picks up" the altitude control, which is consequently shut in every "engine off" dive. On another machine the pilot must remember to shut the altitude control, or when he flattens out after a long dive the mixture will remain as set at a higher altitude, and the engine may choke. Generally speaking, the pilot will throttle down his engine during a long glide and watch his instruments carefully.

The pilot's main duty after landing is to report any imperfections in the engine to the foreman mechanic. Where a rotary engine is concerned, the stoppage should be made by cutting off the petrol supply, so that no gas may remain in the crank case and cause an accidental start when the mechanics get busy. Revolution tests can be made before switching off, and will form a useful guide as to whether any serious adjustments are needed.

A surrendered German bombing aeroplane with a damaged undercarriage. The building in the background is a Zeppelin hangar

Gear Ratios on a Solo Machine.

Why not Solo Gears for Solo Machines? A Plea for Suitable Ratios.

BEFORE expounding my views I wish to point out that by the term "gear ratios on solo machines" I do not entirely allude to top gear ratios: the motor cyclist—we all know him—who rides a $3\frac{1}{2}$ h.p. single on a 4 to 1 top gear and then grumbles (1) because his engine knocks, (2) because he cannot get any speed, (3) because his petrol consumption is high, can turn this page.

The manufacturer professes to give us a machine suitable for solo work and then plays his favourite joke of giving us gear ratios of something like this: $5\frac{1}{4}$, $8\frac{1}{2}$, 15.

For a $3\frac{1}{2}$ h.p. these ratios are preposterous; the top gear is absurdly low, and the drops between gears are absurdly large. Of course, it is quite obvious why makers give us ratios like this. It is because the gear box ratios are designed so as to be suitable for sidecar machines (and apparently for all horse-powers from $2\frac{3}{4}$ h.p. to 8 h.p.). But why should this be so? Surely there is a large enough market for solo machines to enable just one maker to give us a gear box with suitable ratios.

A point in connection with gear box ratios is that a large amount of the bad driving—bad driving, not bad riding—is due to the gear box ratios. In that the rider hangs on to top gear when he should always change down because he knows that his machine will be appallingly slow (and appallingly noisy) if he changes to second. So that the bad driving and the ill-treatment of the machine are due to the supineness of the maker!

As a concrete instance, I know of a $3\frac{1}{2}$ h.p. twin, which is advertised and sold as a solo machine, which is absolutely ruined by its gear box ratios. It is a topping little 'bus in every other respect, but it possesses this fault which makes riding it a toil instead of a pleasure.

It has gear ratios (I am speaking from memory, but the figures are approximately correct) of $5\frac{1}{2}$, $8\frac{1}{2}$, and 16. Sixteen!!

What are Suitable Ratios?

The machine will climb anything and start on quite a stiff gradient on second gear, so that this low gear is never used, which means that the machine has only two useful gears. So for what reason should the purchaser have to pay for and carry about with him this additional pair of gears? (Of course, all this does not appeal to the extraordinary individual whose ambition it is to climb Mont Blanc on a motor cycle; for such a person the sidecar ratios, as fitted at present, are quite suitable.)

To return to our $3\frac{1}{2}$ h.p. twin, or $3\frac{1}{2}$ h.p. or 4 h.p. single, for the matter of that, if it were fitted with three speeds, say, $4\frac{3}{4}$, 6, and the present $8\frac{1}{2}$, it would be, to my mind, ideal. One could then change down early on a hill, keep up the revs. (and the speed), and save the engine, gears, and tyres the unnecessary stress.

There is a gear box, a very excellent gear box, which is fitted to the best of our war mounts, and will be fitted to many of our post-war machines, but it is emphatically not the gear box for a solo machine. It gives ratios (memory again) of approximately $5\frac{1}{2}$, $8\frac{3}{4}$, and 15. This was all very well up the line in France; in fact, I will admit quite frankly that very often the low gear was far too high for me—yes, I was a D.R.—but in England, on English roads, oh! no. Who will ever want a 15 to 1 gear on a 4 h.p. solo machine in England?

The Useless Bottom Gear.

On this war machine, for starting one never needed anything lower than second (unless it was on greasy *pavé*, and the result was usually the same whatever one used). And for hills? Well, I have used second, but not often. Yes, my fellow D.R.'s, I know all about that time you climbed Kemmel Hill, but I am talking of riding on *roads*, not on dirt tracks or boulders.

This particular machine, the 4 h.p. Tr—— (my word, I nearly let it!), was very nice to ride in the back areas on a $4\frac{1}{4}$ to 1 top, but of course one had to change down a good deal in hilly country, which meant dropping to about 7 to 1—many revs and very little speed! If it had had a second gear of, say, $5\frac{3}{4}$, with a low gear of, say, 9, it would have been delightful.

To go into the question a little more technically: to climb a gradient of 1 in 5—about as steep a hill as is ever met with in ordinary road work—with a bad surface requires a tractive force of 550 lb. per ton. If we assume a mean effective pressure of 75 lb. per square inch and a transmission efficiency of 80%, we find that the gear needed for a 500 c.c. motor cycle, weighing with rider 450 lb., is 9.3, which agrees fairly well with my proposed low gear of $8\frac{1}{2}$.

Revenons à nos-boîtes de vitesses! I have not yet tried or examined a four-speed gear box, but apparently it is such as I am asking for, with the loathsome 15 to 1 added to the three useful gears.

So, in conclusion, may I beg Messrs. Gear-boxes, Ltd., to give us poor solo riders a solo gear box for a solo machine?

ARCHIE.

QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Altering a Magneto.

Please let me know if it is possible to convert a clockwise magneto into an anti-clockwise one by fitting a different contact breaker.—P.W.

Yes; by fitting a contact breaker operating in the reverse direction.

Magneto Lighting Sets.

I thought I would make an attempt at magneto lamp lighting, and have an idea as to how it should be done with the following exceptions: (1.)

Could you tell me the approximate voltage generated in the primary circuit when the engine is running at normal speed? (2.) If this current is choked down to suit a five-volt head light, would it be necessary to place a resistance in circuit of tail lamp if only a three-volt lamp is used? (3.) Is it possible to regulate the choking coil in accordance with speed of the engine automatically, and where could I get one for this purpose?—A.J.P.

(1.) The voltage in the primary depends on many factors, and varies in different magnetos and increases so greatly with the rise in speed that it is difficult to give any reliable figure, but ten or twelve volts may be taken as approximate for the class of magneto concerned. (2.) The best way would be to use a five-volt lamp in the rear light as well as in the front; if a resistance is inserted it will only waste current, which might just as well be used in giving light. (3.) Such an arrangement would be very complicated and costly. If you intend going to such an expense and trouble, it would be more satisfactory to get a proper dynamo lighting set. Before embarking on this scheme we would remind you that the energy available in this way from a magneto primary circuit is quite a small amount, and that a good proportion of this must be lost in the transformer, leaving very little for the lamps; also that it is bound to weaken the ignition, especially at low speeds. The accumulator in any case must be charged from a separate source, and by obtaining a larger one and using this to supply the lamps without interfering with the magneto, all the advantages of electric lighting may be had at less expense. What you call a "choking-coil" should really be a transformer. A choking coil for an alternating current is placed in series and consists of a single coil, whereas a transformer is placed across the circuit and consists of two independent coils.

Running Costs.

I use a 2½ h.p. Douglas three-speed 1915 motor cycle (which is my own property) on certain work, the petrol and oil being found me, but I attend to all repairs and cleaning. Would you please advise me what would be a reasonable price to charge per mile for the use of the machine, the amount to cover fair wear and tear and depreciation?—C.J.

You should charge a pair of tyres, say, every 5,000 miles, and add depreciation as 20% for the first year when new and 10% each subsequent year, i.e., 10% of the successively reduced values. A farthing per mile would not be unreasonable.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication.

ILIFFE & SONS LTD.

Gear Box Lubrication.

I have a 4½ h.p. Singer counter-shaft gear machine, which I ride solo. (1.) When running the gears have a very pronounced whistle. Is there any cure for this, and is it advisable to run with grease in the gear box, as there is a hole from it into the crank case? (2.) What size of jet should I use running solo (B. and B.)? (3.) What mileage should I get per gallon? (4.) What kind or make of lubricant would you advise?—H.J.F.

(1.) The trouble may be shortage of oil. It may make some difference if you use oil and grease mixed in the gear box. (2.) We should recommend a .032 jet. (3.) Between seventy and eighty miles to the gallon. (4.) For the engine, any good make of oil for air-cooled engines, such as Prices' Huile de Luxe, Vacuum, Castrol, etc. For the gear box, most motor cycle gear boxes are filled with engine oil, but if the gears are found to be noisy use gear oil; Vacuum C, for example, is a good lubricant. It is best warmed before being inserted, but it cannot be used in the crank case of an engine.

Gears for Sidecar Work.

(1.) I have a 4 h.p. Bradbury, which refuses to pull a sidecar on the top gear of approximately 4½ to 1. Is this gear too high? (2.) I am using an inch belt,

which does not settle down properly in the groove of the engine pulley. The latter is evidently designed to accommodate a 7/8 in. belt, which I find would appreciably reduce the gear. Do you think a 7/8 in. belt strong enough to pull twenty-one stone, including luggage?—G.E.C.

(1.) The gear for a single-cylinder machine should not be higher than 5 to 1, preferably a little lower, say 5½ to 1. (2.) The belt, of course, should not go right into the pulley, but project, say, 1/8 in. 7/8 in. is certainly small. The pulley and rim should be made to accommodate either a 1 in. or 1½ in. belt.

READER'S REPLY.

Cones Working Loose.

I have known this happen to our battery Clynos through the wheel being put in the wrong way round. The back wheel, of course, allows of no mistake.—SOUTHCOMB MAY.

A. NEW MACHINES.

TERMS OF DEALING.

1. We have now settled practically all our contracts for the coming year, and can book your order for earliest possible delivery of New Machines. We require a deposit of £5 with order, returnable if the price we quote to you is increased.
2. We can take your old machine in part exchange. We can arrange an exchange valuation NOW and you can keep and use your old machine until we have the new one ready for delivery.
3. We can hire you a good Second-hand Machine with which to carry on until the new model is ready for delivery, at the nominal cost of 10s. per week.
4. We have definite contracts already placed for

the earliest possible delivery of the following makes:

ALLON, A.B.C., A.J.S., ARIEL, B.S.A., BLACKBURN, CALTHORPE, DIAMOND, ENFIELD, EDMUND, HARLEY, HUMBER, HENDERSON, JAMES, INDIAN, L.M.C., LEVIS, NEW IMPERIAL, NORTON, MORGAN, MATCHLESS, O.K., N.U.T., I.O.M. RUDGE-MULTI, N.U.T., ROYAL RUBY, TRIUMPH, and ZENITH.

5. We can deliver from stock the undermentioned New Machines:

ALLON, 2-speed, 2-stroke	48 gns.
ARIEL, 3½ h.p., 3-speed	£80 0
B.S.A., 4½ h.p., 3-speed, chain-cum-belt ..	76 gns.
CALTHORPE, 2-speed, 2-stroke	40 gns.
CALTHORPE-J.A.P., 2-speed	45 gns.
EDMUND-J.A.P., 1919, 2½ h.p., Enfield 2-sp. gear and clutch, spring frame	60 gns.

NEW IMPERIAL, 1910, 2½ h.p., 2-speed .. 48 gns.

HAZLEWOOD, 4 h.p., 3-speed

ALLDAYS, 4 h.p., 3-speed, 4-stroke

6. Deliveries of further ARIEL, B.S.A., CALTHORPE, JAMES (4½, 5-6, and 2½ h.p. models), LEVIS, and ZENITH machines are expected this month.

7. You will probably have decided by now that you will not stand much chance of getting a machine unless you order in advance. All that you now want to decide is with whom to place your order. We do not want to say that we are the largest London contractors for new machines. This, as yet, we do not know. We can only state that we have on order a VERY LARGE NUMBER of every make, and that we shall not state a delivery date unless we are reasonably assured that the makers can deliver.

B. SECOND-HAND MACHINES.

TERMS OF DEALING.

1. THREE DAYS' FREE TRIAL.—Your money back in full within three days of purchase if not satisfied.
2. THREE WEEKS' OPTION OF EXCHANGE.—Your machine can be exchanged free of charge for anything else from stock within three weeks of purchase, if not satisfied.
3. THREE MONTHS' FULL GUARANTEE.—The same guarantee that the makers give with a new machine.

Our stock of Second-hand Machines is still unequalled in London, and fresh stock is arriving daily.

Any Machine sent on "The Motor Cycle" Deposit System.

RIDER TROWARD & CO.,

31, 40b, & 78, High St., HAMPSTEAD,
N.W.3.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd., and crossed**

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may have equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

FROM January to September last year *The Motor Cycle* dealt continuously with the fuel problem in its various aspects. For years before we had pointed out on every possible occasion the importance of developing and encouraging the home production of fuel that would mean so much should foreign supplies be cut off at any time. The war has conclusively proved the truth of our opinions, and at last both the Government and fuel users are thinking of action along lines that should have been followed long ago.

In various issues we called upon those dependent on fuel supplies for their business or their pleasure, and on those who exist for the purpose of looking after the motorists' interests, to give special attention to the fuel question and to consider seriously what could be done to prevent a recurrence of the unfortunate state of affairs through which we all suffered during the last two and a half years of war. We appealed to the private motorist, and we appealed to the business user of mechanical road transport. We appealed to the manufacturer of motor cars and cycles, and with special vigour we appealed to the private motorists' associations.

The business user has taken action only recently, and the result of his action—through the Commercial Motor Users' Association—has been the suspension of the Government proposals for the taxing of home-produced benzole. This is a great victory, and one from which all motorists will profit. The private motorist has taken action in the forming of a new league to protect his interests—a step that is at present passing through the preliminary stages only. And now the private motorists' association with the largest membership is taking the matter up.

A motor fuel campaign is being undertaken and extensively advertised by the Automobile Association. Stated briefly, the main points of the campaign are State control of fuel prices and encouragement of home production and home-

produced fuels. More laudable objects would be difficult to conceive. Will they be realised? We think they will, but only on one condition, and that is that the universal support of the whole motoring community is forthcoming. All motorists should sign the form and return it to the A.A., for we assume that, although the form is primarily intended for members, the Association will more than welcome support from all.

The necessity for something of the kind is becoming more and more evident every day. Although the Petrol Controller is increasing the amount of fuel which we may hope to obtain, he is not making the fuel any cheaper, and nothing is going to do more harm to all forms of motoring than the absence from the market of a reasonably-priced fuel. The petrol companies have actually told us the price they charge for their product is what the public can be forced to pay, and it has come as a shock to many of us to find that the benzole producers are apparently adopting a similar attitude. They are doing themselves more harm than good, for, instead of building up a market while they have the chance, they are destroying its probability.

Speaking generally, the average motorist may be called a conservative individual—as far as his motoring goes, that is—and he is not going to risk the use of a fuel of which he knows nothing so long as he gains nothing. When he has tried benzole he will be quite willing to buy it at the same price as petrol, because he will know that by so doing he is serving his own interests and also actually cutting down his running expenses, as the m.p.g. with benzole are better than with petrol.

Other home-produced fuels are nearer than many people imagine. Many schemes are on hand, and they are not all bad. The A.A. wants to act as the protector and is well qualified for the rôle—provided that general outside help is forthcoming. We hope that it will be, and commend the whole scheme to our readers for their serious consideration.

Occasional Comments

The Big Fellows.

I AM a little disquieted about present motor cycling tendencies. The financial future is completely uncertain. The 500 c.c. type of machine is temporarily listed at £80 or thereabouts. Optimists glibly assert that by 1923 prices will have fallen 40% or so, and we hope they are right; but a glance at the political situation in this and other countries indicates that in 1923 prices *may* be where they are, or worse. In the meantime, light cars average £300 or so, and even the Ford is £250. These cheaper grades of motor always found their special market among the middle class: and as the middle class sustains a unique and special squeeze-in most tightenings of the money market, the rise in prices coincides with the impoverishment of buyers. So I am driven to speculate about the passenger market, and there are thousands of buyers who must say:

"I want a passenger motor."

"I cannot afford a light car."

"I must choose between a cycle car and a sidecar."

His Decision.

AT the moment there is very little choice in cycle cars. The G.N. is listed at £160-£170; the Morgan at £132-£145; the A.V. at £130 (?); whilst the figures for the A.B.C. and the A.C. Bantam are not announced. There remains the sidecar. The sidecar market falls into two classes—the utilitarian single-cylinder, bought chiefly for heavy duty by men of limited purse: and the two or four-cylinder *de luxe*, which represents everybody's ideal in this class. I cannot see the quondam cycle car or light car man with prolonged experience of high-powered, smooth-running engines reconciling himself to a one-lunger, however excellent. But just as the British machines are supreme in the 500 c.c. sidecar class, so—beyond all question—have the Americans captured public fancy in the 7-10 h.p. sidecar class. Moreover, there is a marked tendency amongst leading British firms to reduce their c.c. The Douglas Co. have won their reputation on 350 c.c. A new and very powerful syndicate is plunging on 400 c.c. We have yet to hear of any really big British concern going out baldheaded for the sidecar *de luxe* market, unless the A.J.S., Clyno, and Matchless people intend to concentrate upon it. I want to see a few of our most capable designers catering for the passenger market, whether by cycle cars or sidecars. Otherwise, just as America has already captured our cheap car market, so will she pinch our passenger *de luxe* market. Tariffs strike me as a coward's castle. We have beaten the world in point of design over almost the whole field of munitions. If we omit the French

75 mm. gun and a certain heavy lorry, we need fear no comparison. I am certain we can sweep the board as masterfully in motor design, given the necessary statesmanship in the framing of policy. At present we are very much on the defensive in the sphere I have outlined, *i.e.*, we have cause to fear that the motorist who wants a vehicle to carry his girl and himself cheaply, swiftly, and comfortably, will send his money abroad.

The Value of Speed Records.

I SEE my colleague "Road Rider" writes slightly of speed records, regarded as a means of informing the buying public. Their usefulness can certainly be over-estimated. Nevertheless, if a machine persistently gains and regains the hour record, I am unquestionably informed that its designer knows his job. He can plan an engine which embodies efficiency and stamina in a very high degree. Moreover, I may take it for granted that he knows how to balance an engine, for an ill-balanced engine is not likely to maintain maximum revs for an hour without trouble. In fact, if I like the 'bus in which he mounts his standard engine, I have only one question left unanswered. Is he an honest man? Does he use a single very expensive "star" engine to advertise his name, and then unload shoddily built 'buses upon a credulous public? Or does he put the brains which inspired his Brooklands 'bus into the perfection of a stock touring machine? In other words, I can size up these speed advertisements by a close inspection of the sister road machine. Finally, it must be granted that it takes a good engineer to design a machine capable of winning the hour record at modern standards, and a good workshop to build a 'bus which will stand the racket.

Hinged Back Axles for Cycle Cars?

READERS of our sister journal *The Autocar* may have noticed that the A.B.C. people have a big sporting car on the stocks, of which the rear axle is a peculiar feature. It is, so to speak, hinged at the centre like the axle of a Sopwith aeroplane undercarriage, and the rear springs consequently run across the track out from the centre of the axle towards the road wheels, the latter comprising the only unsprung weight at the rear of the chassis. This design is based on the following theory: The first duty of a spring is to keep the unsprung weight pressed down upon the road regardless of its inequalities. When the spring's resistance is overcome by a specially bad bump, its second duty is negative in character—*i.e.*, it must not rebound and push the body upwards. With a large unsprung weight (*e.g.*, a very

Occasional Comments.—

heavy axle, two wheels, etc.) a very stiff spring is necessary to road adhesion; but a very stiff spring will push the body up. With a small unsprung weight (e.g., nothing but two wheels) a light spring suffices for road adhesion, and when a bad bump is encountered there is no bouncing, for the spring is too weak to push the body up. This system appears to have distinct possibilities for cycle cars.

A Suitable Transmission ?

IT is no easy matter to devise a suitable transmission for an axle which is in the habit of curtsying amidships. The double bevel pinion drive to a pair of crown wheels is out of the question in a cheap grade of cycle car. Side chains are ruled out by the fact that the sprockets will lean inwards when the axle bows. On the other hand, the divergence from vertical alignment is not too big for belts. I have not lost hope of the final belt drive for cheap cycle cars, and I commend a consideration of this type of axle to anybody who is thinking out a belt-driven four-wheeler. He might further consider the idea of endless belts, with which a breakage would be practically unknown until the belt as a whole was just about worn out.

The Joys of Good Lighting.

CAN remember the days when acetylene lamps were so bad that we occasionally carried an oil lamp in reserve in a box on the carrier. When motor cycles were born lamps were fitted with the spring hinges still characteristic of push bicycle lamps, and the vibration soon broke the hinges. If by any chance the spring survived a long night ride it was long odds against the generator continuing to generate. In these times 10s. 6d. was regarded as a high price for a lamp, and the first satisfactory sample that came my way cost 8s. 6d., and was presumably a Hun, as its name was Schmidt. Then Lucas brought out a glorified push bicycle lamp, with a springless box clip, which

slid over the ordinary push bicycle type of bracket and was secured by a milled nut. This usually worked well until the rigid forks hit a large hump in the road, when the lamp generally did a short vertical climb, and nose-dived steeply to a bad landing crash. Some years ago lamp makers went over in a body to the car type of two-prong bracket and the separate generator. Since when our troubles have chiefly been due to—

1. Impatience during the magic period known as "waiting for the smell." (Irascible individuals turn on too much water and flood the charge.)

2. Carrying a charge of carbide in the generator for months before use. (This reduces it to snuff, and chokes up the valves and the burner.)

3. Absence of a serviceable spare burner. (The burner in the lamp is carboned up. The spare is either in one's pocket, and, *ergo*, choked with tobacco; or in the toolbag, and, *ergo*, choked with French chalk or rubber solution.)

The great merit of the dynamo set is that it is proof against all these little human foibles. Motor cyclists are such careless beings that they provoke acetylene into giving them variegated trouble. But I don't think any of us will dare to carry spare electric bulbs in pockets or toolbags; and on a 1914 sidecar outfit the possession of a dynamo plus a spare bulb spelt almost complete insurance from lighting troubles. We are all palpitating with eagerness to know whether the electricians have evolved suitable batteries for solo sets. Somewhere in England there is a man looking for me with an axe. Early in 1915 I sold him a solo mount fitted with electric lighting. He is now a pessimist. He believes that a future Napoleon with some such name as Schweitzevkoffski will shortly invade England at the head of a united horde of Russian and German Bolsheviks. My lighting set is the key to his dreams. So we are anxious to test those promised solo sets.

RURAL SCENES IN WINTER.

The lady motor cyclist's ideas and desires will in the future have to be considered even more than in the past. The work women have done in the R.A.F. and other branches of the Services has had its effect in creating hundreds of potential buyers of motor cycles.

OUR FIRST JOY RIDE

IT was our first joy-ride. As I tucked myself into the sidecar I asked myself was ever a girl more utterly content than I, on this sparkling winter morning of frost and pale sunshine? Our destination was the little Scottish station seven miles distant, whither we were informed we must go to bring away the New Year hamper that lay there for us, and on the return journey we were to make a *détour* in order to see a house which, according to local report, would provide us with just such a home as we had come into this Highland country to seek.

Contentment.

In Jimmy (my husband) lay the foremost reason of my contentment, since here he was, free once more, and well, after hard service in France. He started the engine, and away we went along the winding road-way. Ahead of us lay the snow-capped mountains, on the far side of which lay Loch X and our destination. There were pike in the loch, and lovingly I fingered the rod and net beside me. If we reached that loch in good time there were heavenly possibilities ahead!

A little while later, with the hamper reposing snugly at my feet, we were climbing steadily up the narrow mountain road which took us every moment further and further from civilisation. How nobly the Scott raced along with its heavy burden! All who know the rhythmic "whirr" of a Scott engine, so like the drone of an aeroplane, will appreciate the keen exhilaration that was ours as, perfectly tuned and perfectly controlled, it bore us on and up. Only once, indeed, has this machine, though possessing two

speeds only, failed us on these steep mountain gradients, and that was on a day when the road was a veritable quagmire, the wind, almost a gale, dead against us, and when, too, we had a heavy load aboard.

On we went. Here a startled rabbit tore across the track in front of us; now a pack of grouse with their blood-stirring cry, "Come back, come back, come back!" flew angrily overhead.

"Oh! for a gun!" called Jimmy, as his keen eyes detected a gorgeous cock pheasant crouching motionless in the tufted grass.

Alone with Nature.

Several times we saw whole families of black cock in whitethorn trees eating the winter berries. Bleak and bare was the landscape now—no sign of human habitation anywhere—just the silvery stretch of road ahead of us cutting its way along the hillside. Numerous black-faced mountain sheep which, not having lived in pre-war days, stared in stunned amaze-

The Scott sidecar on the shores of the "wind swept" loch from which the salmon and pike were taken

ment at the strange outfit approaching, and remembered to turn and run only when we were well past them.

Shortly after noon we were examining every hole and corner of "our house." Originally

Our First Joy Ride.—

there must have been two cottages which later had been built into one, and the result to-day is a rambling little dwelling, unconventional in style no doubt, but well constructed and charming to look upon.

Straightway we fell in love with it, and, finding the interior equally agreeable, decided we would come to terms with its owner at the earliest opportunity. Outside there was a little garage-upon which Jimmy bestowed abundant and detailed attention, while I gave equally engrossing scrutiny to a couple of, good poultry houses, making complicated calculations the while. Beyond these buildings was a stretch of pine plantation, through which unmistakable sounds spoke of a burn. As we approached, a pair of beautiful white-tailed deer broke from cover and disappeared like flashes of lightning into the shadowy depths beyond. Truly this is a country of ever-increasing fascination!

Then, having looked into all practical matters, we sat ourselves on the front door step and feasted—literally feasted—ourselves on the view, as well as on sandwiches, which Jimmy produced from the pocket of an exceedingly grimy trench coat. At our feet lay the loch, wind-swept and immense; wild duck flew overhead; teal chattered on its surface; and on the near shore lay the little green and white boat which was to be ours also. On the far side stretched the

hills, calm and majestic, and on a really clear day it is said one can see right away to the far-off hills.

Soon we were in the boat, the pike rod in my eager hands, while Jimmy gamely looked on from behind the oars, and ten minutes later came the crowning triumph of our glorious day. There was a sudden bending of the rod, out screamed the line, and I knew I had a monster at the other end. As I drew in slowly the strugglings and splashes grew more and more violent, and our excitement surpassed all limits when finally Jimmy landed at my feet a huge—salmon! The first salmon I had ever caught, but—it was out of season! Each of us tried to stifle the insistent calls of conscience. But it was no good. Gently we unhooked the beautiful creature—king of all the fishes—and lowered him into the sparkling water. Then we sighed big, big sighs, and thereafter, as a reward for virtue, caught a couple of fierce but plump pike.

The sky was a fiery, triumphant red behind the snow-covered hills as our "jigger" bore us down the mountain track in the late afternoon, and, as the white-walled cottages of the village in which we are now staying hove in sight, Jimmy and I agreed that it had been a glorious day.

Thus ended our first joy-ride. Truly, with the war at an end, what more can healthy mortals desire than a powerful sidecar in a sporting, beautiful country such as this?

SHEILA.

IN ITALY DURING THE ARMISTICE.

Although the fighting is over our despatch riders find plenty of work to do, and, judging from one of the photographs, they find entertainment also.

OPINIONS.

Notes on the Past, the Present, and the Future. By Prominent Men in the Motor Cycle Movement.

FOURTH SERIES.—Comments of Competition and Other Well-known Riders.

From Mr. Archie G. Cocks, Competition Rider.

DURING my travels up and down the country in the past few months I have heard many motor cyclists voice their views on the type of machine which will be most popular in 1919.

The majority of these riders are more or less of the same opinion as myself—that is, that the only motor cycle worth riding in the future will be of the spring frame variety, preferably with an engine of about 8 h.p.

The transmission must be all-chain, totally enclosed in substantial chain cases, which must be easily and quickly detachable, and, moreover, they must be as quickly and easily attached again.

In the past, we have seen many chain cases which could be detached with ease in five minutes, but these same chain cases took at least five hours, plus five screw-drivers, to attach again, to say nothing about the enormous amount of unparliamentary language.

This type of case must vanish for ever, as I am absolutely certain that the 1919 motor cyclist will have no use for it.

Of course, there will always be a number of motor cyclists who will be unable to afford the above type of outfit, and for these riders a really efficient spring seat-pillar on the machine and a spring sidecar wheel will be demanded.

After very many thousands of miles riding on outfits fitted with either a spring frame or

a spring seat-pillar, I would never again ride an outfit without one or the other.

There is one other type of sidecar outfit which I feel certain will find favour with a small percentage of riders, particularly the elderly ones, and that is the two-seater sidecar with all the controls taken into the sidecar and either steered by means of a wheel or tiller, so that the driver has the same amount of comfort as the passenger.

After many thousands of miles experience in one of these outfits, which I built as an experiment, I have come to the conclusion that, for the elderly rider, and particularly in the winter, this type of outfit has many attractions.

There is one other fitment I feel sure will be demanded by a number of riders for several years to come, and that will be a really efficient paraffin vaporiser, as I am convinced that it will be a long time before petrol becomes really cheap again, if it ever does. At any rate, whatever the price of it is, paraffin will always be about half the price, and to the motor

cyclist who has to consider his running expenses paraffin will always hold out attractions, provided it be properly vaporised.

The two-seater sidecar I have previously mentioned has always run on paraffin or other heavy fuel, and so efficient is the vaporiser that the engine is as good, and develops as much power to-day, as it did the day it was made, and I for one shall continue to use paraffin as fuel until I find a fuel as good as petrol at the same price as paraffin.

From Mr. George Brough, A.M.I.A.E., Trials Rider and Designer.

I AM very optimistic about the prospects 1919 and the following years have in store for motor cyclists. Thousands of pounds' worth of machinery will be diverted from the manufacture of all kinds of munitions of war to the production of motor cycles in large quantities.

Scientific research has shown us how to reduce the weight of our engines, with an increase in power output. New and better shop methods assist standardisation. Concentration by one factory on one model will enable each individual firm to pay attention to the dozens of details which require attention before we can claim that our trusty bicycles are as free from trouble as are high-class cars.

I am of the opinion that we shall soon see the exodus of the luxurious high-powered combination. I think the next show will confirm this. However, the sidecar enthusiast, the potterer, and the business rider will all be catered for when Olympia next opens its doors, and the purely solo man who wants the fastest thing on wheels with complete equipage will find it will not be necessary to buy an over-engineered machine weighing 150 lb. too much, because it happens to have been designed for sidecar work.

From Mr. George King, Popular Clubman and Follower of Trials.

FOR the future of the pastime and sport of motor cycling, I think competitions and trials ought to be made a very strong point, as in the past. Pre-war trials and hill-climbs created the past popularity of the motor cycle, and this kind of encouragement will, I am sure, bring back the old enthusiasm to pre-war motor cyclists and create it for the new comers to our fraternity.

There is no doubt a very great future for the motor cycle, and, with the help of *The Motor Cycle*, a wonderful industry will be ensured.

From Mr. H. Mortimer Batten ("Chinook").

LOOKING into the future, a question of immense importance seems to me to be the problem of road construction. An enormous increase in fast-moving road traffic is bound to take place during the next few years, and one's recollection of the dust nuisance, even in pre-war days, is painful. In the future there will be more motor 'bus services, more road-tearing lorries, more trackless cars, more touring vehicles and motor cycles than ever before; and if there is to be any pleasure in road travelling, if the health of the nation is to be considered, radical alterations must take place in road construction.

Of road users, the motor cyclist is probably the worst sufferer, since he travels at speed without protection, but his case is by no means so bad as that of villagers and country dwellers whose houses are situated at the roadside, and who throughout the summer months are simply enveloped in dust. This state of affairs, apart from entailing financial loss, has done considerable harm to the pastime, and the sufferers do not appreciate that it is not the motors that are to blame—that it is the road authorities for not keeping pace with the times. The motor is inevitable and a blessing to civilisation, and one cannot bring about an evolution in road transportation without the necessity arising for similar evolution in road construction.

There are difficulties. The writer's village, for example, consists of a main street standing on a gradient of about 1 in 16. The villagers refuse to have the surface tarred on account of the resulting slipperiness for their horses: they choose rather to live in an atmosphere of dust—many of them rejoicing in the fact that thereby they derive a real grievance against the motorist! The war, however, and progress in agriculture have removed a good deal of this rural pigheadedness, and it now remains for motorists and anti-motorists to pull together in the direction of general road improvement—a question which involves the health of practically everyone.

From Mr. Eric Williams, D.C.M., Winner of the Last Junior T.T.

I NOTICE, with satisfaction, that some manufacturers are taking up the American system of concentrating on one or two models, making parts standard and interchangeable throughout, so in future let us hope our spare parts will

Mr. Archie G. Cocks.

Mr. H. Mortimer Batten.

Mr. Geo King.

Opinions.—

not want a lot of fitting, which was often the case pre-war. But why not take it further and make chief distributing agents or centres for large areas, say, six or eight, in the British Isles? These centres would do the whole business for their firm in this area in supplying new machines (appointing their own sub-agents), effecting repairs which would otherwise go to the manufacturers, and carry a large stock of spare parts, which could be despatched to private owner or sub-agent within a short time of the known requirements.

Now, regarding competitions, one must admit that in 1914 in many of the trials it was as much an endurance test for the rider as for the machine. This now, when a lot of us have been through the "mill" a little with the Boche, and our health not what it might be, makes us shudder at riding through what we did in pre-war days. If the A.C.U. would take stock machines from the show windows and then put the trade riders on them, we should find results more interesting and useful with less rough riding, and the better standard machine would come out on top; also, it would be much more fair for the private owner competitor.

From Mr. J. S. Holroyd, T.T. and Competition Rider.

IN view of the great interest with which the motor cycling public are awaiting 1919 productions, it seems to be rather an opportune moment to say a few words regarding what I term my ideal mount. To commence with, it must be a turn-out with which I can enter any reliability trial, and the very expression "reliability" infers, to me, an indescribable charm. How many anxious moments have I spent on account of unreliability in bygone days, but never again.

For my power unit, I would like a 1,000 c.c. 60° twin engine having a heavy outside flywheel. I like an outside flywheel for many reasons, not the least of which is that it does undoubtedly obviate indulgence in gymnastic contortions when "starting up" on a frosty morning. Some of my readers may like this form of exercise, but I do not. Again, my simple mind is enthused by an engine which, when required, will just "tick over" with a perfectly equal value in each explosion, and I believe that the outside flywheel will give me this, admitting that carburettor adjustment is good.

For my present purposes, I can afford almost to ignore technicalities, but let me say that the main bearing on the flywheel side must

Mr. J. S. Holroyd.

have a minimum length of at least two and a half times the diameter of the shaft, and on the timing side I would have a ball bearing. This would mean lifelong wear, provided the oiling system were perfect.

So we could carry on with these niceties *ad infinitum*, but lest I should be accused of suffering from mental indigestion, I must hurry through other details. Let the frame be of the loop type, supported by wheels having 28x3in. tyres, Brampton forks, 2½in. tyre clearance in 8in. mudguards, and, mark you, I for one do not want the magneto to share duties with the front mudguard.

From Mr. A. C. Robbins, Successful Competition Rider.

RELIABILITY is the most important item with the majority of riders, and this has to be tested and proved during next season in open competition. In the majority of runs, a machine is only called upon to average 20 m.p.h.; therefore so long as the general appearance of the machine at the start and finish of a trial is good, it stands the same chance as a more speedy and scientific model.

Up to the present the single-cylinder has been the most reliable mount, as witness its wins in nearly all the most important events, and I commend this type to all beginners as the best and most suitable machine. In all my competitions I have ridden a single-cylinder, but if the twin were as reliable I would prefer this type in future. It would have to be a fairly high h.p., so as to take a sidecar when required.

Mr. A. C. Robbins.

Owing to the advanced methods of engine construction, I expect some manufacturers will be able to give us a 3½ h.p. equalling a pre-war 6-7 h.p.

Altogether, I think we can look forward to a very promising and interesting year, and if all goes well the Motor Cycling Club should be able to hold its annual run to Edinburgh next Whitsun.

From Mr. H. O. Wood, T.T. Winner in 1913 on a Scott Two-stroke.

THE popularity of the two-stroke machine has decreased considerably during the past few years, mainly owing to its absence from the ranks of machines used for war purposes, the chief reason being insufficient power. It is probable that the future will give us machines powerful enough even for the most exacting.

To multiply its supporters the two-stroke must compare favourably with the four-stroke on the following points: Reliability, prolonged efficiency, simplicity, accessibility, handiness, balance, acceleration, flexibility, cheapness, and consumption.

It will be generally admitted that the best two-strokes do compare favourably with and even excel four-strokes in some respects, excepting in fuel economy.

Manufacturers in the past have not given this item sufficient consideration, but no doubt they will now turn their attention in this direction.

From Mr. C. G. Pullin, Holder of the Senior Tourist Trophy.

IN my opinion, post-war plans of the majority of engineering firms had not properly matured at the signing of the Armistice, and it will be well into the summer months before the large production schemes, now possible with the present machine tool equipment and factory extensions, get into full swing. Labour should present no difficulty, wages are likely to be high, and also raw materials; but on a substantial output and correct design these should not stand in the way of a good, reliable, and cheap machine.

The greatest question, to my mind, that is not yet settled, is the design. I have recently inspected numerous drawings of machines now in the course of construction, but although being brimful of novelties and fitted with super-efficient engines, all tend towards complication. The man in the street must have simplicity.

I expect to see great developments in two-stroke designs, and if only designers will throw off the cloak of convention and realise that a two-stroke, three-port engine can be equipped with additional valves and made to operate economically without complications, a huge field awaits their product.

Turning to gears, an infinitely variable gear of the hydraulic type is clearly indicated, splendid results now being obtained from comparatively small units, but some time will elapse before these can be produced to meet the requirements of motor cyclists. In the meantime, the best compromise seems to be the epicyclic type, all gears being in mesh and fool-proof in operation.

The finality in frame design has yet to be reached, but pressed steel construction is likely to come forward.

From Mr. Laurence H. Cade, the London Motor Cyclist-Journalist.

THE future must inevitably be veiled in obscurity, but the veil is rosy-hued, tinted from the glow of what lies beyond. Nineteen-nineteen is an alliterative date, easy of remembrance, and it will be a year to remember. It will be the morning of time in the development of a new democracy of the road, for motor cycling will indubitably appeal to the masses as it has never done before.

There will be tens of thousands of initiates of both sexes, and they have to be taught: not taught to drive, but taught the potentialities and the limitations of the types. There will be a tendency, born of the magnificent war services of the motor cycle, to expect too much. We shall see mechanical Shetland ponies hauling pantechicon-like sidecars, unless—well, unless care is devoted to the education of the newcomers.

As an industry, a sport, and a pastime, there is a wonderful future ahead of us.

Mr. Laurence H. Cade.

GEARS AND THE POSSIBILITY OF GEARLESSNESS.

DESPITE the rapid development of gearing for motor cycles during recent years, and the fact that now good and reliable gears are obtainable, none the less we are still far from the ideal. The hub gear came, saw, and was conquered. Suitable for bicycles it was too small for the motor cycle, especially for sidecars, and so gradually became obsolete. The two-speed engine-shaft gear is more reliable, but, projecting as it does from the machine, it is apt to be damaged by a tumble, and as the ratio of reduction is usually about 35% it is unsuitable for heavy passenger work. Omitting a few special types, there are now three kinds of gear in general use—the variable pulley type, the selective chain type, and the countershaft gear box. The first-named, if, as in the Zenith and the Rudge, the belt tension is constant, is easy to manipulate, and fits the gear to the grade beautifully. Its disadvantages are that it involves direct belt drive, and does not give a very low bottom gear, if the top gear be sufficiently high. The countershaft Zenith overcomes these disadvantages, and permits the use of a long belt, but the fact that all variable gears, excepting friction drive, necessitate use of the belt lessens their popularity with many riders.

The Chain Transmission Types.

The selective chain types, like the Enfield, and P and M., are simple and efficient. Being only two-speeders, however, there must be plenty of engine power in hand. A $3\frac{1}{2}$ h.p. with a sidecar needs three ratios, unless one is prepared to do a lot of low gear climbing. With a 6 h.p. engine, however, in good tune, there are few main road hills that cannot be taken on top, and selective gears are delightful easy to manipulate in traffic.

The countershaft three-speed gear box is undoubtedly the most popular type. Its disadvantages are weight and, sometimes, inaccessibility. It needs careful use, and the continual declutching and sometimes double clutching involved are more troublesome on a motor cycle than on a car, since the air-cooled engine is less flexible, and the throttle must be adjusted every time if the engine is not to race or stop. Moreover, the driver has to be more careful than ever with this type of gear in proportioning engine and wheel speeds to each other. To add a fourth speed gives further advantage, but at the expense of increasing the complications of manufacture and the weight.

The writer has owned machines of every type mentioned; and, being in London and continually driving in traffic, prefers his present mount—a 6 h.p. Enfield combination—for that reason. Geared 5 to 1 on top, it is capable of 10 to 50 m.p.h. on that ratio.

At really high speeds it does seem under-geared, but after all 30-50 is a speed one seldom wishes to exceed with a sidecar on war-worn roads, and the 6 h.p. engine geared 5 to 1 is beautifully flexible, and fast enough for all practical purposes. Only for starting and traffic crawling does the writer need his second speed; he has therefore the nearest possible approach to a gearless mount. Except for speed men, pure and simple, a high top ratio is a mistake. Any increase of speed on the level is discounted by the inability to climb much on top gear. The lower ratio will probably be as fast or faster on a cross-country up and down trip, as well as being much more flexible. It is worth sacrificing extreme speed capabilities to get a better all-purpose mount.

Hydraulic Transmission.

The question still remains, however whether it is possible to produce a gearless passenger mount. There are three ways in which the problem may be solved—by steam, by an auxiliary electric motor, and by a revolutionary system of transmission, such as by hydraulic pressure.

The first two are already familiar to Londoners in the National steam 'buses and Tilling's fleet of petrol-electric vehicles. Both surmount stiffish hills, though a trifle more slowly than geared vehicles. Steam is still in the experimental stages so far as motor cycles are concerned, but it seems to have a future, especially in commercial sidecar outfits, where high speed is not required. The auxiliary electric motor adds weight, which might prove too much for a motor cycle; and so far as one can see at present, both types are more suitable for heavy than for light vehicles when speed is more a requisite than power. The third possibility is still in the air, but one may ask whether we must always be tied to the present form of transmission. Is there any mechanical impossibility in transmitting power from cylinder to wheel by hydraulic tubes? It is true that there are a number of practical difficulties, but they are not of such a nature that they can never be overcome. If some inventive benefactor can work his way through them, we should have a transmission like the motor of an electric train, and gears would be unnecessary. Instead of having a form of transmission by which the wheel slows the engine, and gears must be interposed to allow the engine to run fast whilst the wheel turns slowly, we should have a perfectly flexible means of transmission, when all that would be needed would be more throttle opening for the increase of power. The experiences of the last four years have done much towards perfecting the petrol engine. But the ideal transmission still remains to be found.

JULIUS.

SHAFT DRIVE FROM AN ENGINEER'S POINT OF VIEW.

BEVEL, SKEW, OR WORM GEARS?

AN interesting point regarding the question of drive is opened up by the advent of the four-cylinder-in-line engine similar to car practice, and similarly set in the frame. Now up to the present most makers of this type of machine have fitted some form of shaft drive, the exceptions being the friction drive types, which, on account of the right-angled primary drive, are most suitable for a chain final drive; but if we consider that the adoption of a shaft drive entails at least two sets of gears to transfer the line of drive from the central crankshaft to the outside of the road wheel, it will be seen that the question of comparative efficiencies lies between the pair of spur wheels with the shaft bearings and universals and the chain.

As the general run of motor cycles were, and have been since the inception of that means of locomotion, driven by means of belts and sometimes chains, the idea of the more rigid type of drive was, and to a certain extent still is, looked upon as an unnecessary "refinement" and savouring too much of a slavish copying of car practice.

A Pioneer.

One well-known shaft machine, though not English, dating from about 1906, did much pioneer work for the shaft drive devotees. I refer to the four-cylinder F.N., which was really years before its time in many respects. The T.A.C. of about the same date introduced the worm

drive on motor cycles, but as these machines were not built on "sporting" lines they did not succeed as they should have done, principally, of course, because the motor cyclist of their day was culled from the ranks of sportsmen, and the potentialities of the motor cycle purely as a means of transport—of both men and goods—had not penetrated the public's collective skull. Anyway, it was solely in connection with four-cylinder engines that the shaft drive was associated, and the present-day tendency to a big increase in the number of four-cylinder machines on the market should do much to show whether the shaft drive is a desirable proposition generally from the motor cyclist's point of view.

It must not be overlooked, however, that the shaft drive may be applied in a variety of ways. The final gearing may be one of three—worm (either underslung or overhead), bevel, or skew. Any of these will provide a neat looking unit, but the relative efficiencies differ with the circumstances and conditions under which they are employed.

The Longitudinal Engine.

The principal problem, of course, with engines set longitudinally in the frame is to transfer the motion in a parallel direction some distance to one side of the crankshaft. In some cases the first step towards this is effected by the use of spur gears, or bevels, the choice of final drive lying between the shaft and the chain.

The skew gear up to the present has not been used for the final drive and is intended solely for use in positions where the axes of the driving and driven shafts are not at right angles. It may be possible, therefore, to continue the drive to the rear wheel by inclining the shaft to one side and employing skew gears instead of universals and worms.

A very important point to consider in all cases where shaft drive is used is the necessity of employing a universal joint at each end of the shaft to allow for the misalignment during riding, but in these cases their action is only incidental and occasional and does not lower the efficiency of the drive to any great extent, the shaft in the main being in line.

It is also required to have the gear wheel amply supported on both sides so that the liability of "whip" in the shaft shall be reduced to a minimum, and a thinner shaft can be employed; also that the meshing of the gears shall be constant, as the greatest source of noise in gears

is the variation in peripheral speed. The liability of speed variation should also be combated by incorporating in the drive some form of cushioning arrangement similar to that provided in the case of chains. Further, allowances must be made for the reversing and over-running of the machine.

The advantages of the worm are its high efficiency at moderately high speeds—indeed, the higher the speed, up to a certain point, the less the friction and the higher the efficiency—this is possibly due to the better lubricating effect. In all cases the worms should be run in oil baths. Both worm and skew gears are fairly expensive to install—that is, to make a high-class job, but when once properly mounted, with adequate lubrication they are very quiet and retain their good qualities a long time.

Comparison of the Types.

Bevel gears have the advantage of being more easily cut and fitted, but they are noisier than the former two types of gear, and lose their efficiency more rapidly. I have not heard of helical bevels being used on motor cycles, but they are essentially smoother in action and stronger than the plain bevel, and a smaller minimum number of teeth can be safely used. The efficiencies of the worm and skew do not differ greatly, but, if anything, are in favour of the worm; but, as has been seen, with the gear box incorporated, an additional loss is sustained by the introduction of an internal right-angle gear—generally a bevel—so that if a skew gear can be used it will do away with this gear and effect a corresponding saving in power losses, though perhaps slightly modified by the interposition of the two universal joints. As regards the merits of the bevel as against the worm, the bevel has little to recommend it except cheapness of first cost, which personally I consider out of all proportion to the satisfaction obtained from the additional silence, efficiency, and long wearing qualities of the more expensive and better job provided by the installation of a worm gear. MASCOT.

(Left) A pair of spiral gear wheels.
(Right) Helical bevel drive adapted for use on cars.

(Top) Bevel gearing, as used on F.N. motor cycles. (Bottom) Plain worm drive.

PLUG INSULATION.

A PLUG of novel construction has now been fully proved and tested by the Robinhood Engineering Works, Newlands, Putney Vale, S.W.15. The outside insulation of the plug is made from a material which, as far as known, has never before been used for the purpose. It is claimed to be far superior to porcelain, more elastic, non-hydroscopic, and is unaffected by change of temperature within the limit to which it will be subjected.

A SPRAYING JET.

A JET has been recently invented by Mr. W. Javes, Norton Villa, Osmaston Park Road, Derby, the idea of which is to cause the fuel to emerge from the jets in a fine, whirling spray.

As will be seen from the illustration, Mr. Javes's idea is to screw into a plain jet a loose plug, on the top of which are cut a number of helical grooves. Petrol passes through the centre of the plug, issues through the hole midway in its length, thence flowing into the channel provided, and issuing up the helical grooves. The jet is adjustable, and in a modified form is provided with a mushroom head, so that the degree of opening can be instantly altered, and (if necessary) the petrol can be shut off altogether. By this means a very small opening can be obtained, and the objection to a small opening—namely, that it may lend itself to stoppage by an obstruction—can be overcome by quickly opening the jet and again restoring it to its former position, such a procedure being practically certain to clear out any foreign matter.

In a further modification of the invention the area of the jet orifices can be varied either automatically or by hand. A demonstration of the device on a motor cycle would undoubtedly be interesting.

THE MOTOR FUEL PROBLEM.

DR. W. R. ORMANDY, in a paper read before the Institution of Petroleum Technologists, spoke of the growing uses of motor fuels, of fuels solid, gaseous, and liquid, and of substitutes for petrol. Among these are the coal tar distillates from coke ovens and from gas works; shale oil, of the comparatively large resources of this in Scotland, and of the immense deposits running from Norfolk down to Dorsetshire, which are practically untouched; alcohol, from molasses or the non-crystallisable residues from the manufacture of cane or beet-sugar, from starch, from potatoes, cellulose, and sulphite wood-pulp residues; also synthetic alcohol, processes for the production of which

from ethylene and acetylene have been developed. Alcohol, however, cannot be used for the hundreds of thousands of existing motors without admixture of some sort. Motor-benzole mixes with alcohol in any proportion, and experiments have shown that one part of benzole mixed with two parts of alcohol can be employed in existing engines without any alteration whatever beyond arranging for the better heating of the air supply to the carburetter, and possibly a slightly larger jet. An engine provided with such an admixture runs more smoothly than if petrol were employed.

A NOVEL PETROL GAUGE.

AN ingenious and novel petrol gauge has recently been introduced by Simms Motor Units, Percy Buildings, Gresse Street, Rathbone Place, London, W.1. The device is clearly shown in our illustration, which demonstrates a motor cycle tank with the top removed.

It will be seen that the gauge takes the form of a wheel, inside the periphery of which is a triangular float. The wheel is supported on bearings inside the tank, and when the latter is empty the weight of the float naturally remains at the bottom, showing the figure 0, denoting that there is no petrol left. It will be seen that it is easy, therefore, to graduate the wheel in, say, quarts, so that the figure shown in the glass window on the top of the tank will denote the amount of petrol therein.

Since the device consists of only one glass portion, and that an adequately protected tiny window, its working is of the simplest possible description, and it is unlikely that it will give any trouble; but it must be borne in mind that the Simms motor cycle petrol gauge is an article which will not appeal directly to the user, as it cannot be fitted by an amateur, but to the manufacturer, as it must be built into the tank. Sold, however, as a complete fitment, it cannot fail to appeal to the practical motor cyclist.

THE SIMMS PETROL GAUGE.

(Left) The window in the top of the tank through which the figures are clearly seen. (Right) The simple mechanism shown fitted to a tank with top removed.

THE 1919 SMITH MOTOR CYCLE SPEEDOMETER.

THE Smith speedometer has for a long time been popular among motor cyclists, and now that the war is over Messrs. S. Smith and Sons (Motor Accessories), Ltd., 179-185, Great Portland Street, London, W.1, are free to take up once more the manufacture of this excellent instrument. During the last four years the company has been busily engaged in the manufacture of instruments for aeroplane work, which has necessitated the greatest accuracy. It can therefore be surmised that the best possible work has been put into the Smith motor cycle speedometer, which is specially designed to stand hard wear.

The latest model Smith motor cycle speedometer.

RACING IN NEW ZEALAND.

A SPECIALITY of many of the motor cycle clubs of New Zealand is handicap racing on the seashore. As there is no Brooklands on which to test machines at high speeds, the hard flat expanses of sandy beach form an admirable race track for the many thoroughly sporting clubs which exist in New Zealand.

On Saturday, October 26th. at New Brighton Beach, Christchurch, N.Z., the Pioneer Motor and Sports Club held a race meeting. The results are as follows:

8 MILE NOVICE SIDECAR HANDICAP.

1. T. Tyson (7 Henderson) ... scr.
2. H. W. White (7 Harley-Davidson) ... 15s.

Time, 11m. 9s. = 43 m.p.h.

8 MILE NOVICE SOLO HANDICAP.

1. H. W. White (7 Harley-Davidson) ... 15s.
2. A. J. Nicoll (7 Indian) ... scr.
3. R. Brosnan (8 Bat) ... 50s.

Time, 10m. 38½s. = 45 m.p.h.

48 MILE OPEN SOLO HANDICAP.

1. R. Kennett (7 Harley-Davidson) ... 2m. 15s.
2. G. Moffet (7 Excelsior) ... 1m. 30s.
3. H. W. White (7 Harley-Davidson) ... 4m. 30s.

Time, 48m. 58s. = 58.8 m.p.h.

It will be noticed that American machines were to the fore, but, in justice to British makes, it must be explained that there are few, if any, new British machines to be had in New Zealand to-day.

We are members of the

ROYAL RUBY

2½ H.P. 2-STROKE LIGHTWEIGHT

We are producing only one Model 2-stroke Lightweight, viz.: Single-speed, but it will be the best.

SPECIFICATION.—Special Frame with Royal Ruby Patent Safety Stays. Villiers 2½ h.p. 2-stroke Engine. Dunlop Motorcyclette 26" x 2" B.E. Tyres. Dunlop Belt. Brooks Saddle. PRICE £40 NETT CASH.

Deliveries will commence in 3 to 4 weeks.

Place your order early to ensure one.

THE ROYAL RUBY CYCLE CO.,
CANNEL STREET, ANCOATS, MANCHESTER.

Telephones—City 3818—Central 1570.

Telegrams—"Machines, Manchester."

The G.N., originated by Godfrey and Nash over ten years ago, and since then the object of their undivided attention, is the successful outcome of their determination to evolve and perfect a light and comfortable two-seater of high performance and low first cost and upkeep.

Other types of two-seater, the motor cycle and sidecar, the miniature car, and the car-de-luxe, have their certain advantages, and yet fail to fulfil all the conditions.

We have the assurance to assert that the 1919 G.N., in its simplicity of design and sturdiness of construction, sacrifices no essential attributes; it embodies nothing experimental and nothing "microscopic."

An illustration and specification of the "Standard" model will appear in next week's issue; an advance catalogue, with terms, etc., will be posted on application.

DOUGLAS ALL-BLACK MODELS

We have had four years with DOUGLAS Motor Cycles under active service conditions. Our experience and advice are at your disposal. A few of the famous ALL-BLACK DOUGLAS for quick delivery. Guaranteed early delivery of a limited number of 1919 models.

A CUSTOMER WRITES:

11th January, 1919.

Gentlemen,

Thank you for your letter of the 9th inst. with Douglas booklet and petrol licence enclosed. I enclose herewith P.O. for 18/-, the amount paid by you to the Petrol Control Committee for tax on my licence. I note you have despatched the machine. I will let you know when I receive it.

Again thanking you,

Yours faithfully,

If you are interested in DOUGLAS machines call and see us. Always open.

Motor Cycle Police in Canada.

We learn that Montreal has now the largest number of motor cycle police of any town in Canada.

Preparing.

One well-known maker has already sent a squad of competition riders round the last Six Days course on a batch of post-war machines.

Nottingham and District M.C.C.

A committee meeting of the Nottingham and District M.C.C. will be held at headquarters, the Welbeck Hotel, on February 14th, at 7.30 p.m. A most comprehensive programme has been drawn up, and it has been decided to pay more attention to the social side than has been done in the past.

Magneto Exhibition.

An interesting working exhibit of British magnetos has been made by members of the British Ignition Apparatus Association at the Exhibition of British Science Products during the past fortnight at the School of Technology, Sackville Street, Manchester, providing striking evidence of the remarkable development of the British magneto industry.

The Industrial Reconstruction Council.

A conference on "The Workers' Interest in Costing: A Factor of Industrial Reconstruction," will be held under the auspices of the Industrial Reconstruction Council on Tuesday, January 28th, at 6 p.m., in the Hall of the Institute of Journalists, 2 and 4, Tudor Street, E.C.4. The chair will be taken by Mr. Jack Joseph, of Messrs. J. Lyons and Co., Ltd., and the opening address given by Mr. M. Webster Jenkinson, C.B.E., F.C.A., Controller of Factory Audit and Costs at the Ministry of Munitions. Questions and discussion will follow. No tickets are necessary.

Second-hand Prices.

We give below a complete list of the average prices of second-hand machines as advertised in the previous issue of *The Motor Cycle*:

	Previous to 1914.	1914.	1915 and 1916.	1917 and 1918.

GEARS, AND THE POSSIBILITY OF GEARLESSNESS.

No Petrol Permits in India.

The rationing of petrol was discontinued on December 1st in India. This decision was brought about because a regular supply of petrol was expected and there is a considerable stock accumulated in Bombay.

No Sunbeams until May.

Although Messrs. John Marstons, Ltd., were released temporarily from their French military contracts, these have been renewed, which will prevent any Sunbeam motor cycles from being placed on the open market until May next.

Petroleum in Alsace.

Before the conclusion of hostilities the German Petroleum Co. had considerable success in Alsace. A number of wells were sunk, and increased production was anticipated. These oil wells are, of course, now in the hands of our French Allies.

Road Reports.

It is naturally evident that it will take a long time to restore the roads of Great Britain to their pre-war condition of excellence. A good deal has been written on this subject in *The Motor Cycle*, and it is clear that every effort will be made to repair the roads, make new ones, and generally improve the highways throughout the United Kingdom. All this, however, will take time, and for some period ahead there will be stretches of main road in very bad condition which motor cyclists would like to avoid.

We should be pleased to hear from readers in various parts of the country—and we know our readers cover the whole of the British Isles—informing us of any particularly bad stretches in the districts in which they reside, and also any information which would enable motor cyclists who are passing through to avoid them. It is only by co-operating in this manner that motor cyclists can assist one another and get the maximum amount of enjoyment from the pastime.

Returned from Austria.

Basil Vickers-Jones, once famous as a T.T. rider and hill-climbing expert, has returned to England from Austria, where he has been interned since the commencement of the war. When hostilities broke out, Vickers-Jones held an important position in the Eger (Bohemia) works of the Coventry Premier Company.

War-worn Motor Cycles.

At the time of going to press, we received advice that "hundreds of motor cycles" were arriving at Grove Park. It is said that this is the result of the evacuation of Kempton Park, where, as reported in our illustrated article last week, many hundreds of machines of all makes have been parked pending their disposal. We are told that a quantity of these machines (mostly in crates) can be seen from the road, and that they include a large number which have been overhauled by the Army mechanics, and are in good running order.

A Motor Cyclist Aero Engine Designer.

At various times we have given instances of the benefits which the nation has obtained—particularly during the war—as the result of a really close study of motor cycle engine design. It would be interesting, for instance, to know to what extent motor cyclists have contributed to British supremacy in the air. It is known that at least two of the most successful types of air-cooled engines were entirely the product of motor cyclists; and in other designs it is within our knowledge that motor cyclists played a live part.

One of the most successful aero engines of the war was the BR2 nine-cylinder rotary engine designed by Capt. W. O. Bentley, M.B.E., R.A.F., who is one of the three brothers who interested themselves in long-distance records and T.T. Races, in the capacity of amateurs. Capt. W. O. Bentley, whose portrait is reproduced, and who was lately awarded the M.B.E. as the result of his war work, will be recalled as a T.T. rider of no mean repute. The older school of motor cyclist will recollect the name of Bentley in connection with End-to-end records, and it was Capt. Bentley's brother, A. W., who broke the record in 1908, riding a Triumph motor cycle.

In 1909, Capt. Bentley, as a private owner, rode a $3\frac{1}{2}$ h.p. Rex in the T.T. Race. In the following year his mount was a 5 h.p. Indian, but he was again unlucky, a burst rear tyre on Greg Willey's Hill putting him out of the running during the first lap. He subsequently became a partner in the firm handling the D.F.P. car—a French production of very modern design. Prior to the design of the 250 h.p. BR2 engine, Capt. Bentley—at that time a lieutenant in the R.N.V.R.—produced the 150 h.p. BR1 engine. The two engines in general principles are very much the same, having cylinders made up of steel liners surrounded by an aluminium alloy jacket shrunk on, and steel heads.

The Carbide Order, 1917.

Further to the Ministry of Munitions press notice of November 25th, 1918, regarding the restrictions on prices and the movement of carbide, the prices have now been fixed at £30 per ton for lump and £30 10s. per ton for the granulated of 16 to 25 mm. in quantities exceeding 110 lb.

Capt. W. O. Bentley, M.B.E., R.A.F.

THE DISPOSAL OF ARMY MOTOR CYCLES.

Up to the time of going to press, the authorities had not published a definite scheme for the disposal of the bulk of ex-army motor cycles. Forty motor cycles were to be offered for sale by auction yesterday, the 22nd inst., at Messrs. Aldridges, St. Martin's Lane, London.

The BR2 250 h.p. rotary engine designed by Capt. W. O. Bentley, M.B.E. Its forerunner was the 150 h.p. AR1, later known as BR1. This engine was well known in the Service, and has done splendid work.

War Tax Rescinded.

The American war tax of 3% is no longer applicable to the export of motor cycles from the U.S.A. to Canada. This makes a reduction in price amounting to from fifteen to twenty dollars.

Aluminium.

The price of the Government stock of 98-99% ingot is now £150 per ton. The stock will be gradually released so as not to interfere with and disturb the aluminium industry.

Sale of War-worn Cars.

The second-hand motor trade were the chief bidders at the sale of surplus Government cars held at Aldridges, St. Martin's Lane, last week. Very high prices were realised, an old six-cylinder Sunbeam fetching as much as £425 5s. If these prices are any indication as to those at which the Army motor cycles will be sold later on, there appears little hope for the bargain hunters picking up a rideable machine for an old song.

Brooklands.

It is expected that Brooklands will be handed over to the B.A.R.C. by the Air Ministry shortly, but nothing definite or official is at present known. The Brooklands authorities are to settle with the Government regarding necessary repairs to the track with a view to putting it in order at the earliest possible moment. Col. Lindsay Lloyd says he hopes to have the track ready for the summer meetings, and may be in a position to make a definite statement shortly.

The Control of the Roads.

The Royal Automobile Club has established a Parliamentary Committee to consider legislation affecting roads and road transport, with power to act when it is considered desirable. The Club is strongly of opinion that the control of the roads should remain separate and distinct from the control of other means of communication, as heretofore, as it considers that any fusion of such interests, which would necessarily be more or less conflicting, might handicap the development of mechanical traction on the roads.

Programme of the Dublin M.C.C.

The Dublin and District Motor Cycle Club, whose operations for some time past have been suspended owing to the war, is putting its affairs on a business footing, and at a general meeting last week elected officers for the coming year. Those who served the club well in the past were re-elected, Mr. W. H. Freeman again holding the office of hon. secretary. The question of a competitive programme was discussed at some length, and it was decided to hold four road events during the coming season as under: A reliability trial for the Dunlop Cup on Easter Monday, a reliability trial on Whit-Monday, a twenty-four hours' reliability trial at the end of June, and a two days reliability trial on the Saturday and Monday of the August Bank Holiday.

A NEW SPRING FRAME.

A Neat and Novel Device for Gradua Gear Machines.

THE patent files frequently reveal activities in the designing departments of motor cycle manufacturers of which the public know little. Sometimes the publication of a patent specification by the Patent Office is the first and last intimation of certain experiments or ideas. On the other hand, such specifications in some cases herald the advent of a new model. Whichever of these two may be the case in the present instance, a spring frame embodying the Zenith-Gradua gear and a flat twin engine by Mr. Fred W. Barnes are of more than ordinary interest.

It is fairly obvious on examination that the design is more than a diagrammatic drawing such as forms part of the average patent specification, and this strengthens the impression that the flat twin

A spring frame designed for Gradua gear machines. The patent is by Mr. F. W. Barnes, of Zenith fame.

engine is included for a purpose, and not merely to indicate the position of an engine of any type. The countershaft drive, too, is suggested. However, the subject of the patent is the spring frame.

The main part of the frame is a rigid structure. To this is connected a linked wheel frame comprising the bottom tubes and the back stays. The lower ends of the back stays carry bifurcated brackets, which straddle over the bottom tubes and support each a pair of rollers which respectively engage the upper and lower sides of the bottom tubes. These rollers are grooved to prevent lateral displacement.

Coiled tension springs are attached at one end to the brackets, and at the other end are connected adjustably to lugs on the bottom tubes.

THE BUYERS' GUIDE.

Current Prices and Delivery Dates for 1919 Motor Cycles.

Make.	H.P.	Particulars in Brief.	Price.	Delivery.	Make.	H.P.	Particulars in Brief.	Price.	Delivery.
A.B.C.	5	Spring frame.	£ 70 0 0	May.	LEVIN	2½	2-stroke, single gear	£ 33 0 0	January. Out-put booked until end of March.
A.J.S.	3	Twin, 3-speed.	106 1 0	End o. January.	L.M.C.	3½	3-sp. countershaft gear.	73 0 0	} Delivery at end of January.

Chain, Belt, Combination or Shaft?

The Voting on Transmission Systems in the "Which Type" Referendum.
The Fourth Article on Readers' Ideals.

WHICH TYPE?

An invitation to readers was issued in "The Motor Cycle" for November 21st and 28th, to send us the specification of their ideal machine. This referendum represents the opinions of thousands of thinking motor cyclists, and has revealed the proportionate popularity of various engine sizes, types and features in general. Previous articles on this subject have appeared as under: "The Ideal Solo and Sidecar Machines, embodying the Features Most Popular with the Majority," January 2nd. "Engine Types and Sizes," January 9th. "Engine Equipment," January 16th.

THE importance of the transmission question is second to none, therefore the proportionate popularity of the four systems in vogue should provide manufacturers with data of great value to them.

For some time design has tended towards all chain drive, and therefore it will not come as a surprise to readers to learn that the chain led its three rival systems by a very considerable margin.

On the other hand, it is perhaps curious that while in the solo class the four-speed gear box secured the largest number of votes, three speeds were generally considered to be the more suitable for passenger work. The popularity of the infinitely variable gear (such as the Rudge and Zenith) also is clearly indicated in the solo group. The following figures show the proportionate popularity of the various transmission systems for solo machines:

TRANSMISSION FOR SOLO MACHINES.*

Percentage.	From Engine to Gear.	From Gear to Road Wheel.	Percentage.
6.8 ..	Belt	Belt ..	6.8
73.3 ..	Chain	{ Belt. .. 26.2 Chain. .. 47.1	
14.5 ..	Shaft	{ Belt. .. 2.1 Chain. .. 0.6 Shaft. .. 11.8	
5.4 ..	Gears	{ Belt. .. 3.2 Chain. .. 0.8 Shaft. .. 1.4	

It will be seen that all-shaft drive and the gearshaft system together score 13.2%. Incidentally, it should be noted that probably all those who specified all-shaft transmission overlooked that the drive cannot be taken directly from engine to road as on a car, owing to the rear wheel being on the shaft line of the engine; and therefore had in mind the same system as specified by 1.4% only, i.e., gears and shaft.

It is apparent that even for solo work the chain is regarded as the ideal transmission by the majority, while in the sidecar class it shared with the shaft 75% of the total.

SIDECAR TRANSMISSIONS.*

Percentage.	From Engine to Gear.	From Gear to Road Wheel.	Percentage.
1.2 ..	Belt	Belt ..	1.2
66.9 ..	Chain	{ Belt. .. 12.6 Chain. .. 54.3	
25.7 ..	Shaft	{ Belt. .. 0.5 Chain. .. 5.1 Shaft. .. 20.1	
6.2 ..	Gears	{ Belt. .. 1.2 Chain. .. 3.6 Shaft. .. 1.4	

*Excluding infinitely variable gears.

In considering the number of gear ratios; it is at first sight surprising to find that while in the solo class the four-speed gear box found greater favour than the three-speed type, in the sidecar group the three-speed box took first place. This fact appears to indicate that the extra-ratio is regarded as a "top-speed luxury" for favourable conditions. The reason why this desire for such a ratio is more apparent with solo riders probably is due to the fact that the majority of solo enthusiasts specified an engine with a greater reserve of power for ordinary purposes than in the sidecar class.

Further Conclusions.

To facilitate a study of this question we give below figures taken from our review of engine sizes which appeared in the issue for January 9th.

SOLO ENGINES.

Under 500 c.c.	10.3%
500 to 600 c.c.	70.8%
700 c.c. and over	18.9%
	89.7%

SIDECAR ENGINES.

750 c.c. and under	48.6%
Over 750 c.c.	51.4%

In judging these figures it is assumed that sidecars with engines under 750 c.c. capacity have not a sufficient reserve of power to propel an outfit on an abnormally high gear, whereas such reserve exists with a solo machine having an engine of 500 c.c. and over.

The voting on gear ratios was as follows:

	Solo.	Sidecar.
One speed	2.1% ..	1.8%
Two speeds	10.4% ..	2.5%
Three speeds	25.1% ..	48.9%
Four speeds	41.6% ..	39.2%
Infinitely variable	20.8% ..	7.6%

It will be seen that by 20.8% of the solo voters the infinitely variable gear is considered to be ideal. These specifications slightly increase the all-belt drive figures and those representing chain-cum-belt. Taking the infinitely variable gears separately we have the following figures in the solo class:

*All-belt drive	39.6%
†Chain-cum-belt	48.9%
Friction drive	1.3%
‡Hydraulic	0.7%
‡Magnetic	0.4%
No transmission specified	9.1%

* Type as Rudge, Philipson, Wooler.

† Type as Zenith countershaft Gradua gear.

‡ Mentioned as ideals.

In the sidecar group the infinitely variable gears specified include all the above systems and suggested systems in similar proportions.

THE 1919 G.N.

Some Details of the Peace Model of this Four-wheeled Cycle Car.

The standard model G.N. cycle car, fitted with a 90° 10 h.p. air-cooled twin engine, to be marketed at £140.

IT may be recalled that of the many cycle cars which appeared on the market in 1912 the G.N. and the Morgan have been the only two to survive. It has been a case of a survival of the fittest, and since Messrs. G.N., Ltd., have had some seven years' experience in the construction of four-wheeled cycle cars, and have announced their intention to continue the manufacture of this type of vehicle, particulars of the improved peace models will undoubtedly be of interest.

The new models are improved in detail throughout, and the only drastic alteration is the abandonment of the belt drive and the substitution of chains. These are four in number, and provide three speeds forward and one reverse.

As in the older model, the primary drive is by shaft from the engine to a countershaft which it drives by means of a bevel gear, but, instead of a second countershaft driven by chains from the first as in the pre-war type, four chain sprockets are carried on the live rear axle. Three of these carry chains directly from the sprockets on the countershaft, while the chain of the fourth is driven, when required, by a small sprocket on a subsidiary countershaft. This little countershaft carries a gear wheel which is made to engage with a pinion on the main countershaft, and so provides a reverse.

Chassis Details.

The change-speed lever works in a gate and through a selector, the engagement taking place by means of dogs. As the rear axle is of the solid variety, the two internal expanding brakes may be worked independently, so the brake on the off side is controlled by the pedal, and that on the right by means of the side lever. The pressed steel frame is mounted on quarter-elliptical springs. It is interesting to note that the front springs are provided with radius rods extending from the underside of the frame to the front axle. As regards the radius rods at the rear, the forward ends of these are mounted on chain adjusters, so that any slackness in the chains may be easily taken up. To revert to the brakes, the drums of these are 10in. in diameter and are 2in. wide, so that they should possess ample stopping power. Ball bearings are provided where necessary. A distinct improvement has been made in the steering, which is now

on more conventional lines, as the reduction gear is of the bevel variety and wire and bobbin control is no longer employed.

The 1919 G.N. is fitted with detachable wheels and 650 mm. x 65 mm. tyres. The wheelbase is 8ft., the track 3ft. 6in., the overall length 10ft. 3in., the height 3ft. 4in. (with screen 4ft. 1in.), ground clearance 9in., and weight 6½ cwt.

Engine Improvements.

It may be recalled that the pre-war G.N. was fitted with a 90° air-cooled twin-cylinder engine, the bore and stroke of which were 84 mm. and 98 mm. respectively (1,098 c.c.). The latest type is provided with an air-cooled oil sump, the cylinders are held on by four holding-down bolts instead of two; in fact, the whole power unit has been generally improved in detail. The Zenith car type carburettor should make the engine more controllable at slow speeds and capable of better acceleration. So as to get the maximum amount of cooling the cylinder heads project beyond the level of the sides of the bonnet and are thus exposed to the draught caused by the passage of the car through the air. In the old pattern this was detrimental, as the inlet rockers were unprotected from dust, and so liable to wear—a fault which has been overcome in the new model by the provision of enclosed rockers and valve stems. A heavy flywheel is fitted, and the clutch is of simple design, consisting of a single steel plate and two Ferodo-faced plates.

The complete standard equipment which is mentioned in the catalogue as an extra consists of hood, screen, spare wheel and tyre with bracket, electric lighting set (comprising head light, two side lamps and tail lamp, battery, switchboard, and dynamo), horn, pump, jack, tool kit, and number plates. With this equipment the standard car is to be sold at £167 10s., and without it at £140.

There is also another model, known as the Vitesse, which is 100 lb. lighter than the standard vehicle, and is fitted with a specially tuned engine. This model is sold at £195 with equipment and £170 without. The fully-equipped Vitesse G.N. is supplied with a celluloid screen, but there is no hood; otherwise it is fitted out in the same manner as the standard model.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

VARIABLE IGNITION.

Sir,—I have a 1913-14 F.N. 5.6 h.p. motor cycle, fitted with a Bosch magneto (fixed ignition). It seems plain to me that I could get better running if the magneto could be made variable. I wonder if any one of your readers, who is a rider of the F.N., has made this alteration. I should be very grateful for a little advice on the subject.

H.H.T.

THE FUTURE OF SURPLUS GOVERNMENT MACHINES.

Sir,—I think Mr. C. S. Moore's suggestion that discharged soldiers should be given the privilege of buying Army motor cycles is good. Do not limit the purchasers to despatch riders, however, but allow all ranks who were motor cyclists prior to the war the opportunity.

From what I have seen of the majority of despatch riders Overseas, they seem to think that the average Tommy never had a motor bicycle. I have seen things which have made me smile many a time.

I should like to make a suggestion. Could you not have a section in your paper for the real cycle car such as the Morgan, G.N., Carden, and many others, like your Aviation Section, which has been very instructive and interesting?

I may say that I have had *The Motor Cycle* every week since published, and never missed, though sometimes it has arrived a week or two late while on the four different Fronts where I have served during the war.

F. P. CHANTER.

WHICH TYPE?

Sir,—I am one of the old brigade who still think that an 8 h.p. V twin, single-geared and belt-driven, is the ideal machine for touring work.

My 8 h.p. Matchless will do everything I want, and is the most flexible machine possible. Belt drive is absolutely satisfactory with these big engines, whatever it may be with smaller types. It is wonderful what an advantage the 1½ in. variety has over the smaller sizes. My belts regularly run 2,500 to 3,000 miles, and require shortening not more than three times in this distance. I find they can be run quite slack without slipping, and perhaps that is the secret of the satisfaction I have with them.

E. B. HALL.

Sir,—The very apparent success of the "Which Type?" plebiscite provides strong grounds for adopting the measure as an annual undertaking. The importance of a wide field of views cannot be over-estimated, and cannot fail to serve as an efficient weathercock of public opinions. An appeal to motor cyclists every September would receive immediate and enthusiastic attention from every type of keen rider.

In the light of past correspondence as to the suitability of the 3 h.p. twin Enfield for *sidecar work*, there is cause for comment upon the general desire of 500 c.c. for *solo*. During the past seven years I have ridden various h.p.'s, but must candidly admit that a three-speed 2½ h.p. twin Humber tops the roll, and has been undergoing heavy work (two up) for four years, and can still show its dust to a large number of late model 3½ h.p.'s. Both the Humber I have owned have an astonishing aptitude for long life. I shall certainly sample the new flat twin.

A. STANLEY BLICQ.

Guernsey.

SPRING FRAMES.

Sir,—Concerning "Ixion's" comments dealing with the question of spring frames, I am strongly of the opinion that when the correct design of springing has been evolved, of comparatively light weight, though of strong construction, and without that great drawback lateral play, this type of

machine will prove to be actually faster than the fixed frame variety, in that the driving wheel, no matter what the speed, will more readily adapt itself to the condition of the road. Also, by reducing "bounce," it will materially lengthen the life of the rear tyre. I, too, have ridden different kinds of spring frames, only to discover, somewhat to my cost, the unmistakable presence of lateral play; this with but one exception, a little machine, beautifully made, as old as the hills, and of Hun origin, glorying in the name "Wanderer." Among the "nuts" of Hampstead this machine was an outcast, although furtive glances would sometimes be levelled at it when I was not looking. It just bristled with cute mechanical stunts, and the springing of the frame was "it." Tramlines, wet or dry, quickly discover lateral play.

VIC.

Finchley, N.W.

REAR LAMPS ON CYCLES.

Sir,—I enclose for your perusal a leaf out of a contemporary of recent date in which the writer holds forth against D.O.R.A. for compelling cyclists to carry red rear lamps.

This particular scribe has been very venomous in agitating against this infiction, as he calls it, and I would dearly like to answer him in *The Motor Cycle*.

He has been accusing motorists generally of being selfish and domineering, and suspects they will do all in their power to make cyclists carry a rear lamp permanently after the lapse of D.O.R.A. I have written to protest against this attitude, but my letter was not published.

Please do not think the journal to which I refer speaks for all cyclists in this respect, because I assure you, as one of them, I know many will continue to use the lamp in any circumstances, not only because they consider it safer for themselves, but also out of a gentlemanly desire to maintain the true spirit of the road, which prompts them to assist other road users all they can.

CORPORAL ELSIE.

Hereford.

SIDECAR OR CYCLE CAR?

Sir,—Although my experience of motor cycling has been short (I had a little 2½ h.p. two-stroke from about the end of 1915 to the beginning of 1917), this was sufficient to give me a taste for the sport. I am on the look-out for something now that will carry three others besides myself, but the prices of the new medium and heavyweight combinations almost stagger one, notwithstanding the article in your issue of January 16th on current prices. I wish it could be proved that prices are not more than 25% up on pre-war rates. One cannot expect them ever to be at pre-war rates, as the whole conditions have changed, we hope, in many respects for the better; but when what used to be considered a moderate-priced combination is listed to-day at £142 or thereabouts, and a four-wheeled cycle car is going to be produced at £167 10s., the latter, too, complete with dynamo lighting, spare wheel, tools, etc., it makes one hesitate between the combination and the cycle car (or three-wheeled runabout) proposition, and after the present great demand for all kinds of motor vehicles has been reduced, the makers of combinations will have to look out. At least, that is the opinion of one who may be perhaps only an amateur with little road experience; but on paper the combination is losing its attractiveness because of its great increase in price against other attractive propositions.

The best policy, to my mind, for those with only a moderate sum to spend is to "wait and see."

THOS. W. WHITTAKER.

R.P.M.

Sir,—We notice from your issue of December 19th, 1918, in a reference to the Harley-Davidson lightweight, a remark that "the makers claim that the engine attains the highest crankshaft speed of any petrol engine built."

This is very interesting to us, as we are under the impression that the 8,000 r.p.m. attained by an A.B.C. engine holds this record, and we should very much like to challenge, in a friendly way, the engine to which you refer (or any other engine for that matter) to attain, under the same conditions, a higher crankshaft speed than that attained by us at the present moment. A.B.C. MOTORS, LTD.,

GRANVILLE BRADSHAW, Engineer and Manager.

INSURANCE.

Sir,—A few weeks ago I read a short paragraph relating to a new scheme of insurance now being worked in America. By placing a coin or two in an automatic machine a disc is returned, and this covered a riding period of twenty-four hours, but I do not know whether this covered man or machine. For my own part I consider this method far before the ordinary English way. Here, if we pay, say, £3 17s. 6d. for a policy, and by ill-luck we do only two or three months' riding, the insurance pans out at over £1 per month. With the new penny-in-the-slot business riders pay for the *actual riding time only*. Perhaps some of your other readers can supply more details. AUTOMATIC.

Dalton-in-Furness.

THE COMMUNAL GARAGE.

Sir,—I was greatly interested in your article in *The Motor Cycle* of January 2nd on garaging of motor cycles. Some time before the war I wrote to you, suggesting that a firm of accessories dealers should build a place after the style of a public swimming bath, and in the centre of the building have a stores where petrol, oil, and any accessory could be purchased, and round the outside small boxes built to take sidecar or solo machines, which could be hired at a reasonable price for six months.

If some system of garaging were possible in London, it would enable many a young fellow who is in lodgings to have a motor who at present cannot have one because his landlady will not let him bring one into the house.

I hope *The Motor Cycle* will push this topic, so that some of us unfortunate youths can have a taste of the open road, and make an A1 population, as we are very much C3 now. W. C. STEVENS.

THE THREE-JET BINKS CARBURETTER.

Sir,—May I say a few words through the medium of your journal on the somewhat mysterious "dead spot" subject in connection with the Binks carburetter.

I have had considerable experience with various models of this instrument since 1909, and, properly tuned with the correct jets, no "dead spot" occurs during the jet change over; but with wrong size jets there is a certain amount of hesitation and possibly actual stoppage of engine in changing from one jet to another.

For the benefit of your readers and any who may be contemplating the fitting of a Binks carburetter, may I suggest the method of procedure for its fitment? In the first place see that it is the right size for the engine. For instance, a 4 h.p. single-cylinder will require a larger instrument than a 5 h.p. twin, because it has a larger lung or cylinder. A lot of trouble is caused owing to the purchase, from dealers and other agents, of the wrong size and type, making it next to impossible to tune the engine up in a satisfactory manner.

Bear this in mind, as there are at least fourteen different models of the Binks carburetter for motor cycles alone. So, having made sure of the right type, see that it is a tight fit on the engine stump. The next thing is to test the pilot (or smallest) jet by endeavouring to start the engine. If it refuses to start, the jet is too small, so fit a size larger; if it starts and, upon opening the extra air a little, races or appreciably accelerates, the jet is too large, so fit a size smaller.

The same procedure is adopted in tuning up the second pilot jet. Now, on opening to the main jet, if it is a size too small, the engine will hesitate slightly; if it is two or three sizes too small, it will stop altogether. If it is too large, it will unduly accelerate upon opening the extra air valve, and, incidentally, be rather greedy for petrol.

The spring clip at the bottom usually gives the best results with the holes half covered; this has no influence whatever on the first and second pilot jets.

I usually adjust the gas lever so that when it is closed the engine is running on the first pilot jet; it is then impossible to set the levers wrongly in starting, and it just keeps the engine ticking over in traffic. Of course, it can be stopped by opening the extra air lever.

By spending half an hour on these simple experiments one is well repaid by the machine's beautiful running throughout its life, and an easy start off is always obtained without any injections or lifting of the exhaust. Although this carburetter is primarily designed as a single-lever automatic, the extra air lever is there for experiments and varying climatic conditions. A. C. ROBBINS.

ADVANTAGES OF A TWO-STROKE.

Sir,—Anent the ever-returning controversy respecting two v. four-stroke machines, perhaps my experience with a Baby Levis will interest and influence decisions as to choice of a handy knockabout mount. Bought in 1915, second-hand, the motor cycle has been constantly in use in the hilly country around the head of Morecambe Bay. It has an Amac carburetter (first a No. 26 jet, now a No. 20), ignition 4in. advanced, Sphinx mark C25, and two-stroke plug. No difficulty has been experienced in starting, except from stone cold in winter when a thimbleful of petrol (!) through the release valve removes the trouble. Lubricating oil is used freely, but run off from the crank case frequently. The plug is removed for cleaning at intervals of four months, and decarbonising of the engine is not necessary under six

"Elterwater" and his Levis two-stroke.

months. For winter riding a hot air intake is fitted, but for the warmer weather a leather tube extension is used plus an extra air inlet into the induction pipe. The latter removes any tendency to four-stroke, and adds 5 to 10 m.p.h.

Light in weight, the Levis can show heels to anything its horse-power, and delights in rising ground ("Ixion" can say "rot" if he likes), and the makers rightly state "hard work is good for the Levis" (usual disclaimer, please). At speed the "speech" of the engine is akin to an aeroplane, and there being very few two-strokes round this district the hum is well known.

A temporary mudshield is fitted, and also footboards. Consumption usually 110 to 140 m.p.g. Have several times done 150 m.p.g., and this with the apology of stuff sold as petrol. Can any four-stroke do better? The even pull of the two-stroke and total absence of vibration from the engine is delightful, as also is the ability to paddle off.

Carnforth.

ELTERWATER.

AIDS TO STARTING.

Sir,—I read in your columns of the improvement aero engineering is to effect in motor cycle engines, but no one so far has pointed out one drawback. Aero engines are designed on the assumption that nothing but the very best No. 1 petrol will be used in them and the finest lubricants around them. Yet in other of your columns you advocate the use of benzole, alcohol, and mixtures of different kinds in engines designed for petrol. I wonder, sir, if you have tried the substitute nearest to hand, viz., No. 3 war spirit. I have, in one of the most easily started two-strokes on the market (Velocette), and I have given up the wrestling match. I dope it through the sparking plug hole five, ten, twenty times a day.

Yet, sir, in your preliminary account of the A.B.C. you say no kick starter is to be fitted, but the paddle-off method is to be reverted to. Few advertisements of any but very big machines mention a kick starter; the 2½ h.p. Blackburne is the only one I know of. Would it be a legitimate deduction that Mr. Bradshaw and the other designers have never had to use No. 3 spirit? If so, I should be very glad to lend my machine and half a gallon of No. 3 to Mr. B. the next frosty morning, if I may be allowed to watch him "paddle off"—no priming, hot water flannels, or blow lamp heating to be permitted.

Seriously, however, I think designers and makers ought to bear in mind that No. 1 petrol is not always to be had, and that other and home-produced fuels are available in increasing measure if the demand arises. Emergency priming cocks, induction system heaters, and kick starters should be fitted to every machine. Incidentally, the greater the range of suitable fuel available, the more people would buy it, and petrol prices would be lowered by competition.

I have no interest in any cycle, fitment, or fuel, but am merely a very TIRED TIM.
[We also have tried No. 3 petrol, and cannot say that we like it on a frosty morning.—Ed.]

PRICES.

Sir,—“H.L.I.” evidently does not understand the first rudiments of business, which are to buy at the lowest price possible and sell at the highest; also that the value of any article is the price which can be obtained for it.

What reason is there that the dealer referred to in “H.L.I.’s” letter should not put his price up for the combination in question? He has bought it in a favourable market, and the market has risen. Had the market fallen he would not have been able even to obtain his original price. When prices come down, which they are bound to do some time, this agent may have several machines in stock which he will have to sell at a loss. It works both ways, and is the ordinary method of doing business in all trades in which there is a fluctuation of prices.

I should like to add that I have no connection whatsoever with any motoring business.
B.H.V.
Shipley.

Sir,—What a commendable modesty seems to have suddenly developed, almost to an epidemic extent, in the minds of the motor manufacturers of every type: modesty in the sense that they are reluctant to shock the nervous system of the present or potential buyer of the goods they advertise by stating in cold print the selling price. One’s mind is unconsciously carried back to the days of the boom, when many cycle makers supplied their customers with their wares as an act of grace!

This tone largely permeates the “announcements” of a number of present-day advertisers, practically all of whom, of course, have had a good time since 1914, and have participated in the good things the war has provided for them.

We are told that wages have increased enormously, and also raw material costs. The writer, from his own personal knowledge, admits the truth of these statements; but, even so, there are other factors to be taken into consideration by those makers of motors who would seek the favour of the buying public. They, in common with all who have goods to sell, have got so thoroughly used to the daily atmosphere of the past four years of inflated (and often unholy) profits.

It is, of course, common knowledge that many of the smaller fry have to thank the war for their present affluent position, but these will no doubt soon be brought to at least the common everyday level, even though they may not revert to type. But as regards the big firms, they, perhaps not unnaturally, will hope to continue to make the huge profits to which they have now become accustomed; but whether their anticipations will ever be realised remains to be seen, for, after all, the public will have to find the money to provide the profits. Will they be willing to do so? That is a question time alone will answer. It is quite possible that an altogether new type of purchaser will arise out of the topsy-turvydom of this England of ours, and, if so, how far will he absorb the huge outputs which we all hope to see created?

I have had daily opportunities of discussing this price question with a huge number of old motor cyclists—enthusiasts who have been the real backbone of the sport, and who have, quite uncomplainingly, made it possible to

pay the 40% dividends of the pre-war period. They feel, with me, that, instead of makers endeavouring to maintain (and possibly even to increase) such figures of dividend, they should, instead of participating in the general scramble for unholy profits indulged in by every purveyor of goods from wire nails to aeroplanes during the war period, rather take their share of life’s burdens by being satisfied with a reasonable return on their capital. Doubtless it is an absurd proposition to put forward, human nature being what it is, but, after all, the buying public will see to it that no super fancy prices are paid, and thus those makers who are proposing to charge £85 for a motor cycle *worth little more than half that figure* will come down to common earth once more.

So much has the picture of huge post-war demands for motor cycles, and of unseemly scrambles to obtain a machine, whatever the price, been placed before our eyes, that we have almost come to believe it as being true; but we shall see.

I sincerely hope, as do all good Britishers, that all expectations as to output and demand will be realised, but there undoubtedly is a very real danger of output being restricted, to some extent, by the tendency to charge fancy prices. The present policy is certainly likely to have a strangling effect upon the industry, and that we should all deplore.

One other point is that fully 95% of the types that will be offered will be 1914-15 models with a few minor improvements tacked on, as it is common knowledge that the *real up-to-date model will be reserved for the 1920 market*, so that, in addition to paying through the nose for a machine, one will have an obsolete model on one’s hands.

Another disturbing factor both to producer and consumer will be the disposal of the hundreds of thousands of war motor cycles. This element, in conjunction with the revolution both in design and price for the 1920 models, is likely to militate very considerably against the stability of things motoring for the 1919 season, and the makers will be wise to consider well what their 1919 prices shall be.

I rather imagine that all old motor cyclists who buy a new model every year will shun these obsolete types, and purchase where real merit justifies the large capital outlay. This, I know, will happen in a large number of cases, and I rather fancy that some manufacturers will find disappointment permeating the results of their efforts, and perhaps deservedly so.
ROMANESQUE.

Dudley.

Sir,—I have before me “The Buyers’ Guide” for 1919, published in *The Motor Cycle*, and am surprised to read of the high prices asked for post-war models.

We now know of sidecar combinations costing £140 or more, yet cycle cars are comparatively cheap. One would imagine that if motor cycles cost more to produce, so also would cycle cars.

As a result of these prices, I think there will be a “run” on cycle cars, and sidecar prices will have to come down. Cycle cars like the Morgan will be very popular, and I believe manufacturers will have difficulty in making the supply equal the demand. I know personally one motor cyclist who is contemplating the purchase of a three-wheel cycle car, solely on account of the high prices asked for some sidecar combinations.

May I suggest that motor cycle manufacturers lower their retail prices, and be content with a smaller profit? If they do this, they will surely have a greater demand for their productions.
W.

Manchester.

ILIFFE & SONS Ltd., 20, Tudor Street, London. E.C.4
or of leading Booksellers and Railway Bookstalls

QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Benzole as a Fuel.

?

(1.) Is neat benzole easier to start on than Grade 3 war petrol? (2.) Can it be satisfactorily mixed with petrol? (3.) Does it require a special tank? (4.) Does it eat into and spoil the enamelling? (5.) How does it compare with petrol from the point of view of m.p.g. and carbonisation? (6.) Are most garages likely to stock it in future? (7.) What is the bore and stroke of the $2\frac{1}{2}$ h.p. four-stroke O.K. with O.K. engine (m.o.i.v.), 1915? (8.) My crank case release is *via* the hollow crankshaft. What would cause considerable smoke to issue after three minutes' fast running?—F.C.C.

(1.) Benzole gives an easy start, unless actually frozen. (2.) To prevent benzole freezing, it is best to mix it with petrol in the proportion of one-third petrol and two-thirds benzole. (3.) No special fittings are required. (4.) If it is spilt over the enamel, it may destroy it, but if it is wiped off at once with an oily rag no harm will ensue. (5.) The consumption is better and the carbon deposit about the same, though the deposit appears to be of rather a softer nature. (6.) We expect so. (7.) The bore and stroke are 70x70 mm. (8.) Probably the vaporisation of the oil in the crank case, due perhaps to a slight excess of oil. If the smoke is excessive there may be leakage past the rings.

Registration.

?

(1.) I purchased a Rudge-Multi clutch combination numbered M4204. The seller informs me that the machine has been in his works for three years or thereabouts. It has not been registered by him, and he does not know who the man is or what steps he has taken about the number. What should I do—try to get the number transferred to me or get a new number? If the former, to whom should I apply? (2.) The machine was driven to me (about twenty miles) a few days ago and was then going well. I cannot now start it, even after heating the cylinder and carburetter with a blow-lamp and injecting petrol into compression tap. Can you suggest a method of starting? (3.) On pressing down the starting pedal—with all closed—there is a slight hissing noise, indicating a leakage about the top of the cylinder head, which is apparently bolted on. Does it require a new washer, and if so, of what should the washer be made?—J.F.G.

(1.) You should write to the Clerk of the County Council of Cheshire, Chester, and ask for the number to be transferred to your name. He will then send you a form to sign, with the request for 1s.—that is to say, if the number has not been already cancelled. If it has been, you will have to re-register the machine, which you can do with any County or Borough Council in the United Kingdom, paying a fee of 5s. (2.) It is just possible that the fibre bush in which the rocking arm of the magneto works has swollen through damp. You should therefore remove the contact breaker cover, rotate the engine and watch if the rocking arm is moving. (3.) Admission of air at this point may account for the difficult starting, and a new washer is required. These washers are usually copper and asbestos.

pression is fairly good. Up to now I have been using B.B. oil. (3.) I have never been able to get more than 70 m.p.g.; now I cannot get 40. (4.) How should the magneto be timed?—G.C.

(1.) We should say that the jet in question is rather too large, and you might try No. 31 or 32. A single-point plug with substantial electrodes should not cause pre-ignition. (2.) It is quite time to take the engine down, grind in the valves, clean out the carbon deposit, fit new valves if such are required, and generally overhaul the engine. (3.) It is rather hard to say why the petrol consumption should have gone up; 70 m.p.g. is quite good, but of course the consumption you speak of is ridiculously high, and you might try a smaller jet, as first of all suggested. Probably there is a leak somewhere. (4.) The magneto should be timed in the following manner: Place the piston exactly on top of the compression stroke and connect up the magneto with the points just about to break and the ignition lever two-thirds retarded.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication.

ILIFFE & SONS LTD.

Knocking and Overheating.

?

I have a 1915 $3\frac{1}{2}$ h.p. T.T. Rover (fixed engine), fitted with a Philipson pulley and B. and B. carburetter, 34 jet. Is this the correct size? I use a single-point aero plug. My greatest troubles are knocking, overheating, and high petrol consumption. It is geared $3\frac{3}{4}$ to 1, and is very fast when in good order. (1.) After running about a mile the engine gets very hot, and at the first incline starts knocking. Retarding the spark and closing the air does not ease the knocking much, but makes the engine lose power. Will you please tell me the cause. I have just fitted a new carburetter float because the old one leaked, and this had no effect on the knocking, but gave more power. (2.) Do you think I ought to take the engine down and grind in the valves? The valve tappet clearances are correct, as I have tested them. I took the engine down twelve months ago, and it has not done a great deal of work since, so I do not think carbon deposit should cause the overheating. The com-

RECOMMENDED ROUTES.

NEW CROSS (LONDON) TO HULL, VIA WOLVERHAMPTON.—F.H.

Regent's Park, Finchley, Barnet, St. Albans, Redbourn, Dunstable, Fenny Stratford, Stony Stratford, Towcester, Daventry, Dunchurch, Coventry, Birmingham, Wednesbury, Wolverhampton, Bloxwich, Brownhills, Lichfield, Burton-on-Trent, Derby, Nottingham, Newark, Lincoln, Brigg, Croxton, Hull.

AYR TO HENDON (LONDON).—S.R.

Ayr, Ochiltree, Cumnock, Sanquhar, Thornhill, Dumfries, Annan, Longtown, Brampton, Alston, Newbiggin, Barnard Castle, Scotch Corner, Boroughbridge, Wetherby, Aberford, Doncaster, Bawtry, Retford, Newark, Grantham, Stamford, Alconbury, Eaton Socon, Biggleswade, Baldock, Welwyn, Hatfield, Barnet, Finchley; at Church End (Finchley) take the right-hand fork for Hendon. Approximately 380 miles.

MILLOM TO TAVISTOCK.—J.H.B.

Milom, Broughton, Gethwaite, Greenodd, Newby Bridge, Kendal, Lancaster, Preston, Wigan, Warrington, Tarporley, Whitchurch, Wellington, Bridgnorth, Kidderminster, Worcester, Tewkesbury, Gloucester, Stroud, Nailsworth, Bath, Wells, Glastonbury, Durston, Taunton, Cullompton, Exeter, Okehampton, Tavistock. The surface is likely to be rather better *via* Moretonhampstead and Two Bridges, but this is an exceedingly hilly road.

Dissolution of Partnership.

Messrs. the Eastern Garage Co., of Forest Gate, E.7, advise us that a dissolution of partnership having been mutually agreed upon between Mr. J. L. Love and Mr. Chas. E. Lovett, the latter, as sole remaining partner, will carry on the business.

A Rumour Denied.

For some time there has been a persistent rumour that the A.J.S. Co. is intending to market a light car. There is no truth in this rumour, and the Wolverhampton firm will continue to concentrate on the sidecar machine.

Change of Title.

We are informed that the Forward Motor Co., the manufacturers of the Forward sparking plug, will in future be known as the Forward Sparking Plug Co. The proprietorship of the company and its general trade policy will in no way be altered, the change of name being merely to indicate the nature of the business.

[Burberry's Peace Year Sale.

Burberrys, Haymarket, are now holding a sale of weatherproof garments. Included in the sale are a number of Service weatherproof garments and several articles of naval and military equipment which have either been used as models or left on hand in the course of the year's business.

Henderson Motor Cycles.

We are informed that Mr. T. W. Henderson, the manager of the sales department, the Excelsior Motor Manufacturing and Supply Co., the makers of the American Henderson motor cycle, will shortly visit this country. Mr. Henderson is intending to stay in Europe indefinitely as the European representative of his company, and will have his headquarters in London. The London representatives of the Henderson are Messrs. Robertsons, 157b, Gt. Portland Street, London, W.1.

Catalogues Received.

Messrs. Alldays and Onions' preliminary catalogue for 1919 is to hand, and is rather more complete than the average advance list. The Allon two-stroke motor cycle is fully described and illustrated by upwards of a dozen pictures.

A well got up and usefully compiled catalogue has been published by the Hoffmann Manufacturing Co., Ltd., Chelmsford, Essex. This gives minute details of their numerous ball and roller bearings, many of which are suitable for motor cycles. The catalogue may be obtained on application to the company.

We are in receipt of the advance 1919 list of Wooler motor cycles, published by the Wooler Engineering Co., Ltd., Alpertons, Middlesex.

Where Benzole may be Obtained.
Messrs. Selfridge inform us that their motor department can now supply benzole in two-gallon cans.

The Enfield Two-speed Gear.

We are advised that the Enfield Co., Redditch, is again in a position to accept trade orders for early delivery of its two-speed gear.

Rudge Preparations.

Preparations at the Rudge-Whitworth works for a very large output of motor cycles are rapidly progressing, practically all this company's munition engagements being completed.

Fire at Birmingham.

We regret to learn that the premises of Messrs. S. Smith and Sons, Ltd., at 122, Alma Street, Birmingham, were completely destroyed by fire on the morning of the 10th inst. Customers are requested to be good enough to address their enquiries to the London address of Messrs. S. Smith and Sons, Ltd., 179-185, Great Portland Street, W.1.

The Premier Runabout.

Messrs. Coventry Premier, Ltd., advise us that they have received over a thousand enquiries concerning their new runabout from the announcements which have appeared in *The Motor Cycle*. We are asked to state that the advance list is not yet ready, and that, owing to the abnormal conditions prevailing at the present time, it is impossible for them to write to each applicant pending delivery of the list.

The Bluemel Programme.

Messrs. Bluemel Bros., of Wolston, near Coventry, advise us that they are continuing to manufacture the same accessories as before the war. In addition, they are putting on the market an improved form of windscreen, which, from experiments carried out, effectively protects the sidecar passenger from the wind and rain in anything but a very heavy storm.

C.A.V. War Work.

The firm of Messrs. C. A. Vandervell and Co., makers of the well-known C.A.V. magneto, have during the last four and a half years manufactured many devices which have helped us to win the war. Mr. H. A. Midgley, the company's chief engineer, evolved a wonderful little fuse for trench warfare, which has been used successfully in the Stokes trench gun, while other fuses for aeroplane bombs and hand grenades were also manufactured. Many tanks were equipped with C.A.V. starters, which were also fitted to "M-L's." A special type of starter magneto for aeroplanes was also made. Curiously enough, one of these was found in a captured German aeroplane, and it is now back at the C.A.V. works. C.A.V. electric lamps were used for numerous purposes—in a very neat, compact, and simple signalling set, for example, and in tank lighting installations. While Mr. Vandervell himself stayed at his post at the works, all his brothers and his eldest son joined the Colours. One of the brothers, Maj. Frank Vandervell, served in the Tank Corps.

Valve Mechanism.

The object of this invention is to provide improved means for mounting protecting cylinders over valve rods and springs. These covers are provided with external tapers on one or both extremities to engage with internally tapered fixed members and adjustable nut members. The internal taper on the abutment, engaging with the external tapers, presses

the constituent parts of the cover together, and secures them in position. The covers or cylinders are made in two parts, and are held together by the adjustable taper members at the lower extremity.—F. A. Kimberley and the James Cycle Co., Ltd., Birmingham, No. 117,235, July 11th, 1918.

A Leaf Spring Fork.

In this design only one pair of links is used and the springs are approximately vertical. With this device two distinct motions are obtained, one in a vertical and the other in a longitudinal direction. It is not altogether a good-looking fork in the form shown here, and probably the springs would be exposed to the mud thrown up by the front wheel, but these points can be modified, and do not affect the feasibility of the design.—G. Rigby, Manchester, No. 117,300, July 12th, 1918.

A spring fork patented by G. Rigby, of the Royal Ruby Company.

THE House for NEW & SECOND-HAND MACHINES

A. NEW MACHINES.

TERMS OF DEALING

1. We have now settled practically all our contracts for the coming year, and can book your order for earliest possible delivery of New Machines. We require a deposit of £5 with order, returnable if the price we quote to you is increased.
2. We can take your old machine in part exchange. We can arrange an exchange valuation NOW and you can keep and use your old machine until we have the new one ready for delivery.
3. We can hire you a good Second-hand Machine with which to carry on until the new model is ready for delivery, at the nominal cost of 20s. per week.
4. We have definite contracts already placed to

the earliest possible delivery of the following makes:

ALLON, A.B.C., A.J.S., ARIEL, B.S.A., BLACKBURN, CALTHORPE, DIAMOND, ENFIELD, EDMUND, HARLEY, HUMBER, HENDERSON, JAMES, INDIAN, L.M.C., LEVIE, NEW IMPERIAL, NORTON, MORGAN, MATCHLESS, O.K., N.U.T., I.O.M. RUDGE-MULTI, N.U.T., ROYAL RUBY, TRIUMPH and ZENITH.

5. We can deliver from stock the undermentioned New Machines:

ALLON, 2-speed, 2-stroke	48 gns.
ARIEL, 3½ h.p., 3-speed	280 0
B.S.A., 4½ h.p., 3-speed, chain-cum-belt	76 gns.
CALTHORPE, 2-speed, 2-stroke	40 gns.
CALTHORPE-J.A.P., 2-speed	45 gns.
EDMUND-J.A.P., 1919, 2½ h.p., Enfield 2-sp. gear and clutch, spring frame	60 gns.

NEW IMPERIAL, 1910, 2½ h.p., 2-speed .. 48 gns.
HAZLEWOOD, 4 h.p., 3-speed 79 gns.

6. Deliveries of further ARIEL, B.S.A., CALTHORPE, JAMES (42, 5-6, and 2½ h.p. models), LEVIE, and ZENITH machines are expected this month.

7. You will probably have decided by now that you will not stand much chance of getting a machine unless you order in advance. All that you now want to decide is with whom to place your order. We do not want to say that we are the largest London contractors for new machines. This, as yet, we do not know. We can only state that we have on order a VERY LARGE NUMBER of every make, and that we shall not state a delivery date unless we are reasonably assured that the makers can deliver.

B. SECOND-HAND MACHINES.

TERMS OF DEALING.

1. **THREE DAYS' FREE TRIAL.**—Your money back in full within three days of purchase if not satisfied.
2. **THREE WEEKS' OPTION OF EXCHANGE.**—Your machine can be exchanged free of charge for anything else from stock within three weeks of purchase, if not satisfied.
3. **THREE MONTHS' FULL GUARANTEE.**—The same guarantee that the makers give with a new machine.

Our stock of Second-hand Machines is still unequalled in London, and fresh stock is arriving daily.

WELDING Broken Cylinders, flanges, combustion heads; immediate attention; reasonable prices.—Below.

WELDING Aluminium Crank Cases, gear boxes, by experts of 11 years' experience.—Below.

CYLINDER Grinding on latest machinery installed since hostilities ceased; accuracy guaranteed; new pistons fitted.—Sadgrove and Co., 140, Conybere St., Birmingham. [X0803]

IS Your Car or Motor Cycle hung up for repairs? We will buy it as it is.—Railway Garage, Staines. [2872]

WELDING—Broken cylinders, pistons, connecting rods; cylinders rebored, new pistons and rings.—A. Pilkington and Co., 390, Lichfield Rd., Birmingham. [2198]

FRAME Repairs and Alterations—Special frames and tanks built, any designs; enamelling and plating.—A. Pilkington and Co., 390, Lichfield Rd., Birmingham. [2198]

PAINTING, body building, conversions, hoods, and screens to clients' requirements; quick deliveries; quotations with pleasure.—Palmer's Garage, Tooting. [1991]

GROVER, Smith and Willis, Basingstoke, will make a first-class job of your repairs. We have a fine machine shop and welding plant, and skilled mechanics. [2599]

CENTRAL Motors (Oldham), Ltd., undertake to thoroughly overhaul and repair any make of motor cycle.—Below.

BROKEN Frames, forks, crank cases, connecting rods, pistons, cylinders, etc., etc., welded by the process of oxy-acetylene. Send your enquiries. All work guaranteed.—Below.

WE Repair all makes of gear boxes, N.S.U. gears, etc. All repairs promptly attended to.—185a, Huddersfield Rd., Oldham. [2694]

BIRMINGHAM—Motor cycle overhauls and engine repairs and tuning; highest power guaranteed; magnetos overhauled; quotations free; work executed promptly.—St. George Motor Co., 44, Erasmus Rd., Sparkbrook, Birmingham. [X2481]

WELDING, Brazing, and all class of general repairs; work guaranteed; enquiries solicited.—D. 26, St. Lawrence Rd., N. Brixton, S.W.9. [2862]

N.S.U. 2-speed Gears—We execute repairs to these gears promptly, and supply replacements for all types.—Eagles and Co., Acton Hill Works, Acton, London, W.3. [X9676]

SWIFT of Coventry, Ltd., undertake the thorough repair and overhaul of any make of motor cycle at their large and well equipped repair works, 132-134, Long Acre, W.C. Enquiries invited. [7931]

HUB Gears—Armstrong and Sturmeys motor cycle hub gears repaired and parts supplied; repairs and overhauls of Triumph engines a speciality.—G. A. Dalby, 60, Baker St., Sparkhill, Birmingham. [X1753]

The Sporting Single.

DESPITE the undoubted advantages of the clutch, the reliability of chain transmission, and the convenience of a change of gear ratio, there is still a large coterie of motor cyclists who recall with affection the single gear mounts of a decade ago. In developing the motor cycle as a machine for the multitude, the rider, the trade, and the A.C.U. together have gradually changed it from an ultra simple sporting mount into a single track vehicle embodying most of the elements of a car. That it serves the purpose of the majority in its latter form goes without saying; nevertheless a large demand still exists for single gear solo mounts such as were in vogue in 1909, plus, of course, increased engine efficiency and more scientifically designed frames.

Ten years ago the average motor cycle was a single cylinder single-gear machine weighing about 170 lb. and costing something under £50. The appeal of this class of machine lies in its comparative simplicity, light weight, and high speed. In addition, the light rear wheel enhances the charm of the machine by playing no small part in its powers of rapid acceleration and general "nippiness," which are absent when a machine has a rear wheel embodying a clutch or made heavy for more serious work.

Again, there is nothing to equal the all-belt drive for silkiness of running. Present-day belts should give no trouble whatever on solo machines, and it is to be hoped that the lost popularity for all-round purposes will not be responsible for the entire abandonment of the all-belt drive by the trade.

We are constrained to refer to this type of machine because, at present, there appears to be a tendency for makers to produce only a double purpose "single," and to discontinue the manufacture of the old 500 c.c. type in favour of an engine a little larger. To render these machines suitable for sidecar purposes, they are made heavier than is necessary and desirable for

solo use, and have a gear box and transmission which are only essential for passenger work. In other words, these dual purpose machines are sidecar models which can, if desired, be used as solo mounts and not, as they were a few years ago, solo machines with light sidecars attached.

This, of course, is as it should be, as by these methods it is possible to give greater satisfaction to the majority than would be the case if the machine were only a "makeshift" when used with a sidecar. Nevertheless, it should not be overlooked that a large percentage of the original demand for the sporting single-gear belt-driven machine still exists, and, in addition, a large number of potential buyers of such machines join the motor cycle ranks every year.

The Control of the Roads.

THAT the development of self-propelled traffic is one of the most urgent reconstruction problems is without question. Motor vehicles will be among the most important factors in the restoration of commercial prosperity of the country. Therefore it is the duty of all motor cyclists, as an important section of the motoring community, to take an intelligent and definite interest in the present legislative proposals. The situation is, briefly, that a Ministry of Transport is being formed, under the leadership of Sir Eric Geddes, which proposes to control the roads and bridges of Great Britain, and there is a very serious danger that such a proposal will be rushed through Parliament before the public realise the measures that are being imposed on them. The greatest danger lies in the fact that Sir E. Geddes is a railwayman, and he is surrounded by others with the same interests. We must see that the roads do not suffer the same fate as the canals. The bigger motoring organisations are beginning to take action, but unfortunately individually instead of collectively. We must strengthen their hands, and above all urge unity of action.

Occasional Comments

Bigger Two-stroke Engines?

I SUPPOSE that eventually the motor cycle engine will need as little attention as a push bicycle, and that this ideal will depend partly on improved design and partly on the use of improved materials. Studying a diagram of the A.B.C. cycle car, it occurred to me how extremely foolproof and easy to keep in repair such a chassis would be if it were equipped with a two-stroke engine. The transmission is already so simple that no driving skill is required, and that refacing the discs is the main item of repairs. Impose upon such a transmission a two-stroke engine with a magneto drive so arranged that it can only be replaced in the right position, and you get an incredibly foolproof 'bus at an extraordinarily low manufacturing cost. Of course, the snag is that as yet we have not made two-stroke engines exceeding $2\frac{1}{2}$ h.p. which would keep cool without the aid of water. If big air-cooled two-strokes come along, they will lower engine costs and reduce normal engine maintenance to mere decarbonisation.

Advances in Two-stroke Cooling.

AS the stationary air-cooled four-stroke engine has advanced from, say, 8 h.p. to close on 400 h.p. during the past five years, two-stroke enthusiasts may be pardoned for hoping that a proportionate increase in the maximum size of an air-cooled two-stroke cylinder has occurred. There is little evidence on the point. Two-stroke engine design has been practically stagnant. A good deal of drawing office work has been done, and a few experimental engines have been made and run. None of them has set the Thames on fire. It is premature to hope as yet for even an engine such as would simplify the cycle car mentioned above. On the other hand, every advance in cooling affects the two-stroke *pro rata*. I think we may hope to see in 1920 motor cycle two-stroke engines of fair size which do not bake their piston rings, or require decarbonisation every 750 miles, or render their sparking plugs incandescent on bad hills, or depend on lashings of oil to prevent seizure.

A War Incident.

IN 1914 a firm designed and built an ambitious bicycle with what passed as a real walloping air-cooled two-stroke engine in those days. It never went into production for the simple reason that it would not run for more than half a mile under roadster conditions. Not so long ago the makers confessed their worries to an engineer whom they supposed to be a leading light in air-cooled aero engine design. In actual fact none of his aero engines had made good—from that standpoint he was something of a failure. But he knew quite enough about cooling to transform the 6 h.p. cycle engine. He gave its makers a few tips, and when their bantling next took the road it toured quite obediently with a sidecar! This incident

is significant. There are at least three British aero engines of different makes which have beaten the world in air-cooling on the grand scale. If a designer who knows the principles underlying one of these engines from A to Z could be induced to concentrate on the two-stroke —? There is unquestionably a tendency amongst designers in general to consider the two-stroke. For example, a leading firm of car manufacturers have had an experimental two-stroke car on the road for months. Several aero engineers are busy in the same direction. It is not easy to be sure what perfected two-strokes might offer us, seeing how crude pre-war two-strokes were in comparison with four-strokes. But at least it is certain that the two-stroke is a far cheaper manufacturing proposition, and also that it is very considerably simpler for an owner to maintain.

1919 Prices.

I AM not one of those who suspect that the manufacturers are profiteering. Admittedly, £50 for lightweights and £80 odd for a $3\frac{1}{2}$ h.p. tourist solo are "some" prices compared with 1914. Admittedly, also, it is the custom of vendors in all trades to grade their prices with an eye upon demand. One friend of mine intends to market a car, the price of which will not be settled definitely until he has "felt" the demand. He can turn out 1,000 chassis per annum, and if he gets 1,000 orders the price will be the minimum at which he can make a fair profit, e.g., £750: but if he gets 2,000 orders the price will be £1,250 or so. Suspicious riders recognise that there is an unprecedented demand for machines, and fancy that makers are taking advantage of the situation. I never hesitate to go for the trade when I feel like it, and my proprietors allow me considerable latitude in that respect: but I hold the trade absolutely guiltless at the present moment. The prices of commodities are up about 100% on the average: motor cycle prices are up about 25-33%—it is astonishingly little. Moreover, there is an excellent reason why every maker must offer us the best and cheapest proposition in his power. 1914 reputations have to be confirmed, if not regained, after a five years' moratorium. They have to compete with the wares of mushroom firms, lately engaged on munitions. Some of these mushroom firms possess magnificent resources—brainy staffs, skilled hands, huge shops, modern machinery, big capital, and special experience in aero work. In 1914 we could take it for granted that the tiptop firm of 1913 would be near the summit in 1914. In 1919 it is just possible that a firm which did not even exist in 1914 may top the motor cycle tree. So the buyer is, for the nonce, master of the situation. His old tyrant, the firm who kept him waiting for delivery in 1914, has to win his custom and his confidence all over again. Firm and customer are in much the same position as one of those quaint divorced couples in

PELMANISM IN 1925.

BY A BUSINESS MANAGER.

In the Pelman lesson dealing with Imagination and how to turn it to account occurs the following sentence: "It is by the power of Imagination that we are enabled to picture what might be." After re-reading this during one of my periodic reviews of the Course, it flashed across my mind that it would be interesting to attempt to visualise what Pelmanism might be in 1925.

So rapid has been its progress during the War that one can do no more than speculate on what will be the exact position of Pelmanism a few years hence, though it is fairly easy to foresee some of the results of the spread of this System of mind and memory training.

A SHORT REVIEW.

Let me remind readers quite briefly of one or two facts concerning Pelmanism. A quarter of a century ago it was unknown. For years its advance was slow—it was too new for most people. They scoffed at the idea of mind training; said it couldn't be done. But its founder, Mr. W. J. Ennever, and those associated with him, lacked neither courage nor hope. Sooner or later, Pelmanism would earn the recognition which was its due; of that they were confident. During the three or four years immediately preceding the War Pelmanism was just coming into its own. It remained for the War, however, to work that change in our mental outlook which has given Pelmanism its real opportunity. In the fifty-one months since August, 1914, as many people adopted Pelmanism as during the previous twenty years, while since the Armistice was signed the daily enrolments have been greater than ever, and the half-million total in the membership of the Institute is now within sight.

A MINISTRY OF PELMANISM.

Thus my imagination pictures the establishment of a Ministry of Pelmanism, working in close harmony with the Ministries of Education, Labour, Overseas Trade, and other departments of the Government. Pelmanism will then occupy a prominent position in the curriculum of our Elementary, Secondary, and Public Schools, while every teacher will be a qualified exponent of its principles and their application, not only to the study of other subjects, but also to the problems of after-school life and work. "Going to school" will be shorn of its terrors and become a true delight to the children. Their ordinary lessons will gain so much in interest through Pelmanism that the task of the teacher will be considerably lightened.

I conceive, too, that, that every boy and girl over school age will be required to work through the Pelman Course, and pass an examination on its teachings as a part of the vocational training which, we hope, by that time will be a feature of our national life. So many of the employers of 1925 will be people who are now studying the Course and will benefit from it during the years just ahead of us that it will no doubt be a common practice to insert the stipulation "Must be a Pelmanist" in their advertisements in the "Situations Vacant" columns of the newspapers, for, by 1925, it is practically a foregone conclusion that the superiority of the Pelman-trained man or woman will be universally recognised, no matter what his or her occupation may be.

MILLIONS OF PELMANISTS.

In my mind's eye I see Pelmanism making inevitably greater and greater headway each year, until in 1925 its adherents are numbered by millions, even if no move has been made in the meanwhile to nationalise the study, as has been repeatedly suggested in many quarters. But I cannot imagine five years—and five of the most fateful years in the history of the British Empire—passing before some definite step is taken by Parliament towards making Pelmanism a part of our national education.

EXIT THE SCOFFERS.

No great movement has made progress without arousing a great deal of opposition. Pelmanism is no exception. Yet it seems to me that another five years will witness such a thinning of the ranks of the scoffers and sceptics who now, through sheer ignorance, deride Pelmanism, that no anti-Pelmanist will dream of airing his views in 1925 for fear of being considered eligible for a lunatic asylum.

A PELMANISED WHITEHALL.

At the risk of being considered a visionary or a super

super-optimist, I think we might count within the realms of possibility the reorganising and reconstruction of our Governmental Departments on a Pelmanistic basis. The examples of business efficiency provided by two or three of the newest Ministries have raised hopes in some of us, and surely, with Pelmanism on the flood-tide, we can look forward to the time when all the departmental cobweb and red tape will be swept away, leaving behind only organisations which will be of a real service to the nation.

And here my imaginings must end. These somewhat scrappy views of what Pelmanism might be, and might be doing, in 1925 may appear far-fetched and rather ridiculous. Blame my enthusiasm for Pelmanism for my foolish optimism, if so you describe it, but remember at the same time that, six years ago, nobody would have dared to predict that Pelmanism would occupy the eminent position it does to-day.

WHAT "TRUTH" SAYS.

Let us now attempt to summarise the points which emerge in a survey of the present position of Pelmanism. The first is the enormous extension of the work done by the Pelman Institute. Pelmanism is to-day a household word. The little grey books which contain its teaching are being carried all over the world wherever the English language is spoken. In Mesopotamia and Macedonia, on nine sweepers and battle cruisers, men of all ranks are busy in their leisure moments training their minds to a higher efficiency. And at home men and women of all classes are just as earnestly striving to make themselves mentally fit. A roll of a quarter of a million students is something to boast about, a roll of a quarter of a million* contented students is a matter for justifiable pride.

The second point that stands out prominently is the recognition of the value of Pelmanism which is being bestowed upon it by those interested in public education and the public welfare. A third notable point is found in the fact that the advantages of the training offered by the Pelman Institute are being ever more largely sought for other reasons than financial, business, or professional advancement. When first dealing with the subject *Truth* suggested that there was no class, however highly placed or expensively educated, which could not profitably adopt Pelmanism, that it was more than an avenue to business efficiency and promotion, since it offered a means of real intellectual development.

This phase of the training is shown to-day to have aroused the interest of a very numerous class. The leisured classes of both sexes are now studying Pelmanism in ever increasing numbers with satisfaction to themselves. Distinguished Pelmanists are to be found on the roll by hundreds.

All ranks of the peerage are represented, the judicial bench, eminent men in all the professions, sailors, soldiers, and diplomatists, leaders in society and social service are finding out that through Pelmanism life can be made fuller and rounder.

In all the correspondence one detects only one note of regret—that the student had not made the acquaintance of Pelmanism sooner. On the other hand, the mental results chronicled are of manifold diversity. Self-realisation, extension of interest in life generally, mental stimulation, increased clarity of thought, a greater appetite for knowledge, a source of new ideas, are some of them which alone would justify *Truth's* recommendation of Pelmanism as an intellectual and social factor of undeniable importance.

* Now 400,000.

Full particulars of the Pelman Course are given in "*Mind and Memory*," which also contains a complete descriptive Synopsis of the 12 lessons. A copy of this interesting booklet, together with a full reprint of "*Truth's*" famous Report on the work of the Pelman Institute, and particulars showing how you can secure the complete Course at a reduced fee, may be obtained gratis and post free by any reader of "*The Motor Cycle*" who applies to the Pelman Institute, 199, Pelman House, Bloomsbury Street, London, W.C.1.

In answering this advertisement it is desirable to mention "*The Motor Cycle*."

B.L.I.C.

“The Magneto Pre-eminent”

ON CARS and Motor Bicycles, on Aeroplanes, Lorries, and Tanks—under the most exacting War conditions, the British-built “B.L.I.C.” has fully proved its pre-eminence.

We trust you will specify the “B.L.I.C.” Magneto for your post-war requirements.

**THE BRITISH LIGHTING AND
IGNITION CO., LTD.,**

Proprietors: VICKERS, LIMITED,

204, Tottenham Court Road, London, W.1.

Occasional Comments.—

America, who are flirting with a view to re-marriage. For twelve months at least, gentlemen, the makers will do the wooing, and it is the buyer who will be coy. As for the agents—well, I dare say *they* are dreaming of premiums: and considering what Barmecide banquets their showrooms have offered for 4½ years, I can feel for them.

The "Tiny Tot."

WHEN we find standard roadsters fitted with 350 c.c. engines capable of 60 m.p.h., and a 220 c.c. engine ready to develop 5 b.h.p., the "tiny tot" brigade, who clamour for an 80 lb. potter-about jigger, appear to be within sight of their goal. Ever since the 1⅓ h.p. Clement-Garrard bicycle of 1903, weighing 70 lb., there has been an insistent demand for very cheap featherweights, and a steady trickle of production to meet it. The dimensions of the demand are unverifiable, but it is probably big if a good machine can be turned out at the right price. The Auto-wheel and the motor scooter are the latest examples: the latter is a freak: the former is not over-powered, and in other characteristics falls a shade short of current standards. Still, a lot of water has passed under the bridges since the last tiny tots made their *début*, and I think the position to-day is that a good little one is apt to cost as much as a good medium-sized one, and that the tiny tots are still looking for a suitable transmission.

The Little Fellow's Needs.

WE can certainly get an engine of the required power at the required weight, and a good engine at that; the chief bother is that the magneto and carburetter will weigh as much as the rest of the engine put together. I once bought a brand new French carburetter from Gamage for ros. 6d.; it weighed under 1 lb. and worked tolerably well. If somebody could produce a vaporiser of this kidney, and somebody else would do as much for the ignition (*i.e.*, a flywheel magneto), the wee engine would be about right. Then comes the trouble that little engines want rather special transmission. Garrard used twisted raw hide belts with steel hook fasteners, and a fixed gear of about 7 to 1. When the belt slipped, you twisted it more tightly; when it pulled through you chopped the end off, untwisted it a bit, and pierced a fresh hole. The modern rider will not stand this. He insists on variable climb-all-hills gears, and there must be no fear of slip. Moreover,

AS THEY REACH THE DEPOT AND AS THEY EMERGE.

A Douglas as it is dumped at a salvage repair shop in the West of England, and one of the repaired machines—rebuilt, enamelled, equipped, and tested for the road.

as the wee engines only attain their high power output by revs, a variable gear is actually a necessity. Hence it is next to impossible, as yet, to provide a cheap; featherweight transmission.

Air Leaks in the Induction Pipe.

NOT long ago I saw a huge aero engine, on which a very simple provision against air leaks at induction joints was employed. The pipes bolted to each inlet valve port were "stubs," cut off short; and they were connected to the main carburetter manifold by giant rubber insertions, tightened round the pipe-ends by strong band clips. This flexible joint is cheap to make, overrules all small errors of alignment, and permits the erectors to concentrate in securing a good joint at each cylinder port. I think it is worth adoption on certain multi-cylinder motor cycles, which have bad reputations in this respect. The tip is easily tested, without greater risk than the possible scrapping of an inlet pipe implies. On some V twins there is hardly space for a rubber insertion of adequate length, but the idea is easily applicable to any flat twin.

A Big Sporting Twin.

SOME years ago I chanced to handle Jake, de Rosier's 90 m.p.h. racing Indian, and ever since I have wondered whether our own trade would ever evolve a really light sporting twin. In the old days we did not bother about variable gears, huge lamps, big carriers, etc., and one of the early single-gear 5 h.p. Bat machines, for example, probably weighed less than the average modern 3½ h.p. roadster. Nowadays, a machine has little chance of finding customers unless it possesses a variable gear. The consequence is that by the time a maker has equipped a sports twin it is nearly as heavy as the roadster model, and can only be distinguished by dint of o.h.v. or a dropped handle-bar. Now a stripped twin of 5-8 h.p. offers us some of the very finest sensations in the motor cycling gamut. Such a machine should differ from the roadster model in the following respects:

- (1.) Hot-stuff engine. (2.) Maximum weight reduction.
- (3.) No equipment except stand and toolbag.
- (4.) Short frame and special steering. (5.) (?) Single gear. I add the last item rather tentatively. I can only speak for myself. It is a very bad hill which I cannot climb with 5 h.p. and an adjustable pulley, and on a sports mount I prefer the lightness of such an outfit to the weight of two chains and a gear box.

The Orbit magneto, enclosed with cams and gears.

MAGNETO DRIVE AND POSITION.

An Important Point in Design Reviewed.

THE magneto is, perhaps, the most important unit of a motor cycle engine. It is also a most delicate piece of mechanism, and probably the least understood part of the machine. It is, however, appreciated by most riders that, to give the best results, a spark should be produced during a certain definite fraction of a second.

That some machines have the magneto in one position and others in a totally different place appears to pass unnoticed by the large majority of owners. If a magneto is located where it is bound to receive more than its full share of mud and wet, the rider may complain because he has to clean its exterior, but he rarely thinks what influence the position may have on the efficiency of the engine.

Some magnetos are driven by a chain, some by gears, and a few are shaft-driven. At one time the accepted practice in both twins and singles was to fit the magneto in a low position at the front of the engine, and to drive it by a cycle chain. This position and transmission system will be found on many of the best modern machines, yet the thinking motor cyclist will not agree that it is ideal. Designers, of the latest twins, have brought the chain-driven magneto to the rear, but on the representative singles of to-day the low front position is still retained. One cannot say that this is due to any fact which proves it to be the best position—in fact, one may say that it is the worst—but since the machines so fitted are among the most reliable, it would seem that the magneto has now reached a degree of weatherproofness that, from a mechanical standpoint, it is no longer necessary to consider its position.

As regards the transmission, this is another matter. Reliability is only one point in efficiency, and as it is necessary for the spark to occur when the piston is at a

B.S.A. MOTOR BICYCLES

TESTIMONY FROM FRANCE.

"The B.S.A., as you know, is standard in the French Aviation, which has many hundreds in use. I must say the poor machines have, on the whole, a very bad time and are driven very hard—the majority of their drivers had no previous motor cycling experience, are rather careless and 'fast'—everybody seems to ride them and to learn to drive on them, including officers—nearly always a sidecar is attached. Despite such drawbacks it is marvellous how the machines succeed in performing useful work in despatch riding, postal service, provisioning, and conveying passengers. One may say now that, before the B.S.A., all sorts of machines had been tried from small twins to big American Motor Cycles, and that under such handicaps they all failed to be of any real use.

"In conclusion, I feel I owe a debt of gratitude to the machine which has carried me so faithfully, through fair and through foul, for two years of war. She is still sound although a little disreputable looking, as you will judge from the enclosed photos."

Yours truly,

ROBERT SEXE,

Motocycliste Etat Major.

Catalogue Post Free.

THE BIRMINGHAM SMALL ARMS CO., LTD.,
SMALL HEATH, BIRMINGHAM.

The 1919 G.N., True to Type.

The G.N. has always been a successful example of the simple and straightforward cycle car. Its design has always been based on sound and well-tried principles. As a result, it not only survives as a notable example of the simple and efficient type, but has, in some respects, been even further simplified and tidied up.

Specification.

ENGINE.—The engine is the 90° air-cooled twin, which has been fitted to the G.N. since 1912.

The G.N. engine is vibrationless, the running balance is superior to the balance of an ordinary four-cylinder engine.

Its two cylinders, 84 x 98, give a capacity of 1098 c.c., and the G.N. system of air-cooling, with deep cooling fins and arrangement of inlet and exhaust valves, gives excellent results. The engine is placed across the frame, and the cylinder heads and exhaust ports are very thoroughly cooled by the full and direct air draught.

A large external flywheel is fitted, and gives very steady running and slow pulling.

The rockers operating the over-head inlet valves are entirely enclosed in a neat casing, cast integral with the dome.

The cylinder heads are easily detachable, and their extreme accessibility enables carbon deposit to be removed in a few minutes.

The engine is mounted in the frame by a system of three-point suspension.

LUBRICATION.—G.N. system of semi-automatic pump, delivering direct to crank-shaft bearings, air-cooled sump to crank case.

TRANSMISSION.—Through 3-plate G.N. clutch to bevel-driven cross-shaft, thence by Renold roller chain to rear axle. Drive is taken through only one chain at once, and all changes are made by substantial hardened steel dog clutches. The transmission is simpler even than on the past Grand Prix models.

SPRINGS.—G.N. semi-cantilever springs with radius rods.

STEERING.—A neat steering gear box is fitted with bevel-gearing.

WHEELS.—G.N. detachable and interchangeable wire wheels, 650 x 65, with spare wheel and bracket.

WHEELBASE.—Standard 8ft., Vitesse 8ft. 6in., track 3ft. 6in., over-all length 10ft. 3in., width 4ft. 2in., height 3ft. 4in., with screen 4ft. 1in. Ground clearance, 9in. Weight, standard, 6½ cwt. Vitesse, 5½ cwt.

PRICES.—STANDARD model, without equipment .. £140 0

Ditto with complete standard equipment .. £167 10

VITESSE model, without equipment .. £170 0

Ditto with complete Vitesse equipment £195 0

FURTHER PARTICULARS, WITH FULL SPECIFICATION, TERMS, ETC., WILL BE GLADLY POSTED ON APPLICATION

G.N. LTD., ETNA WORKS,

HENDON,
N.W.4.

The Moto-Reve twin engine with gear-driven magneto at the front of the engine.

A certain amount of backlash exists also with a train of gear wheels, especially if they are incorrectly cut or are supported in bearings that are worn. Therefore it would appear that to overcome this the best form of magneto transmission for a four-stroke engine is a shaft directly connected to the magneto, and driven by a single half-time wheel off a pinion on the engine-shaft. This would eliminate all sources of backlash but one, i.e., between the teeth of the pinion and half-time wheel.

Probably this backlash is not a disadvantage sufficiently great for the designer to consider removing it altogether by fitting a flywheel type of magneto. Of late there has been a marked tendency for motor cycle designers to consider this system, and undoubtedly ere long we shall see flywheel magnetos on English machines. In these cases, however, as in those of American motor cycles fitted with them, increased efficiency has not been the chief consideration. Their introduction is due more to endeavours to reduce the cost of production.

When one reviews the variety of magneto positions in general use, the number is astonishing. First of all, there is the old conventional single-cylinder design, with the magneto below the front

certain point in its stroke, any backlash on a chain would tend to alter the ignition timing at certain moments. This tendency must exist with a chain, however nicely it is adjusted, and the longer the chain is, the greater the tendency will be, because the drive is not always exactly positive.

New Hudson twin with chain-driven magneto at the rear of the engine.

The American Excelsior twin with gear-driven magneto below the front down tube.

An American flat twin with diagonally placed magneto.

A shaft and worm-driven magneto on a single-cylinder engine—the 1914 T.T. Premier

down tube and driven by a chain, such as the Triumph, Ariel, Blackburne, B.S.A., Villiers two-stroke, Levis, L.M.C., Precision, etc. Then there are those with a chain-driven magneto at the rear of the cylinder, as on such designs as the Rover, Sunbeam, Alldays, and the Star.

The Star design is interesting as showing a chain magneto transmission designed with a chain case integral with the crank case.

In twin-cylinder machines having chain-driven magnetos, the low front position was practically standard practice prior to 1915, as representative of which may be mentioned the J.A.P.

The Rex machine, however, had the magneto before the engine and within the diamond frame.

Since 1915 designers appear to have favoured the rear position. The Lea-Francis was one of the earliest V twins having the magneto behind the engine.

On the Sunbeam 8 h.p. military model,

An eccentric (l) drive suggested by a reader.

The gear-driven magneto at the rear of the Humber engine.

A Rex design, with chain-driven magneto in front, but inside the frame.

is transmitted to the magneto sprocket. Presumably, there would be a bearing to support this load.

After the chain, the gear-driven magneto is the next stage in development. Here, again, we find the position

of the magneto varies considerably. It is significant, however, that very few English designers have placed a gear-driven magneto in that low front position so common with those machines employing the chain. The W.D. single—an engine of very promising design—embodied this position and form of drive; while the M.M. and Excelsior American motor cycles also have a gear-driven magneto placed below the front down tube of the frame, but in English designs the gear-driven magneto is

The P. and M. twin with vertical shaft-driven magneto

the magneto is placed high up in the diamond frame, and is supported on a platform carried by the rear down tube. Here it is certainly out of the way of mud and wet, but perhaps full accessibility of the rear cylinder valves has been impaired.

The A.J.S. design carries the magneto still further rearwards, the position being behind the rear down tube, where it occupies a space otherwise not used. In both these designs the chains seem to be somewhat long, and we may look to future models being modified to some extent in this respect.

A neat design with a chain-driven magneto at the rear of the engine is the Alldays twin, in which the chain is enclosed in the integral timing case.

In the flat twin group, the only chain-driven magnetos appear to be the two latest horizontally opposed engines, i.e., the Victor flat twin engine unit and the Raleigh.

One of our illustrations depicts a magneto driven off the main transmission chain—that is, forming one point of a triangle. We cannot imagine this design being very satisfactory, as the entire "pull" of the engine

The Alldays twin, with enclosed chain drive for the magneto.

A M.A.G. twin with shaft-driven magneto at the rear.

A French twin with gear-driven magneto placed between the cylinders.

The P. and M. inclined engine with chain-driven magneto at the rear.

usually placed well above the centre of the crank case.

In the single-cylinder group, the James, Premier, and Clyno two-stroke designs have the magneto at the rear of the cylinder, employing a train of gears, of which generally the cam wheel is one. The Rudge, F.N. single, Bianchi (Italy), J.E.S., and Flying Merkel (U.S.A.) are among those having a gear-driven magneto in front of the cylinder.

In twins, the gear-driven magneto is not so common in English designs, but most American machines, both singles and twins, employ gear wheels.

The usual position of the magneto on American machines is at the front of the engine, but on English and Continental designs it is more often at the rear, while on the old Alcyon (France) a centrally placed magneto was gear-driven.

The 8 h.p. military Sunbeam, with chain-driven magneto at the rear. In this position the chain cover detracts from accessibility of the tappets of the rear cylinder.

The gear-driven magneto is general practice in opposed twin engines, the Raleigh and Victor excepted. Always the magneto is placed over the crank case, and, with one exception, in a vertical position. This exception is the American Bayley-Flyer, in which the ignition unit is inclined to the rear.

The shaft as a magneto transmission is not so uncommon as may be supposed. The 2½ h.p. Enfield, Motosacoche, Bat, Pope (U.S.A.), and the 90° twin P. and M. are among the twin engines employing it; but in the single-cylinder class the Diamond is the only English standard

Probably the difficulty of placing a complete unit in the frame has much to do with the small number of English twin machines employing gears. The Premier 3½ h.p. even firing V twin embodied a gear-driven magneto, as did also the latest design of this concern's 7.9 h.p. engine. In both these designs the magneto was placed at the rear of the cylinders, while the Moto-Rève had a gear-driven magneto at the front of the engine.

magneto in a central position, and employs a vertical shaft and worm gear, which form of gear was also part of the design in the Pope and the Cleveland lightweight. In the Motosacoche, Diamond, and Bat designs, bevel gears were used, while the Puch has spiral gears.

It may be remembered that the Bat, which embodied a shaft-driven magneto, had the ignition unit right above the engine—in fact, in a chamber in the tank. Probably this was the only machine in which was revealed full appreciation of the necessity to keep the magneto clean and dry, at a time when most motor cycles had this delicate instrument placed within a few inches of the road.

The variety of magneto positions and transmissions appears to have come into existence entirely on account of convenience. It is true that the low front position was due, in the first place, to the fact that it was practically the only position available on the machines, to which the magneto was fitted as an after-thought. The machines were not designed to carry a magneto, and it is certain that had it been necessary to apply power to the earlier ignition systems, frame designs would have been altered to accommodate them, when, in all probability, the low front position for the magneto would not have been considered.

In the meantime, there is no decided tendency toward any particular system of magneto transmission. It may be said that the chain appears to be most popular with designers, which probably is due to the extra cost of a train of gears, which, in addition, is difficult to make as silent as a chain.

An American two-stroke lightweight with magneto flywheel.

Impressions of a Motor Cyclist Mechanic in India.

A Comparison of British and American Motor Cycles.

SGT. ALGY DENDY, writing from The Fort, Kohat, N.W.F., India, makes some enlightening remarks on the design and behaviour of machines on the Indian roads. In spite of the big pull American makes have had during the last few years in Overseas markets, the British motor cycle is still looked upon as the finest machine in the world, excelling in wearing qualities. Sgt. Dendy says:

"I have been sergeant-instructor in workshops attached to an armoured motor battery, and have had a good deal of repair work to do to motor cycles of both the two and four-stroke variety.

Dust and River Beds to Consider.

"Comparing the American motor bicycle with the British, it scores in comfort owing to its larger wheels and tyres, and its weight holds it down well. But it is tricky in the dust, and especially in crossing dry river beds. The controls to the gear and clutch are awkward when passing camel and mule convoys. Camel convoys number anything up to 200, and are usually in single file, which means a lot of gear and clutch work. On the narrow roads the heavy Americans want a lot of holding up, and their steering lock is much too small. Getting astride a Triumph after one of the big twin

Tappets on most engines are worn more than anything, the large type, such as fitted to the 1912 Triumph, being an exception.

"Bowden wires are not nearly hefty enough. Small two-strokes with no key-

Sergt. Algy Dendy,
M.M.C.C.

ways on which to fix the flywheels are an endless trouble. I have had to cut many keyways and fit keys before they would stop on.

"The most comfortable machine I have ridden out here is a 4.5 h.p. Zenith. This seemed so nicely balanced that it was like sitting in the middle of a sea-

saw, and that is just the thing for this district.

Exceptional Petrol Capacity.

"Undoubtedly the ideal machine for this part of the country for solo riding would be a W.D. Triumph, with 28 x 3 tyres, dust and wearproof tappets, and, above all, another type of spring fork. Also, tanks holding four and a half gallons of fuel would be a boon, as petrol is sold in four-gallon drums.

"For the sidecar, something very much more hefty in frames is needed, and, more than anything else, a spring sidecar wheel.

"Quite a nice testing ground here in the summer is the climb to the top of the Kohat Pass, rising 1,100 feet in seven miles, starting with a river bed crossing, and then about two dozen bends, very nearly hairpins, with overhanging rocks and precipices at the corners. These bends prevent speeding, and mean a lot of middle and low gear work, the sort of hill on which one would like a fourth gear—between top and middle.

An Opportunity for British Manufacturers.

"In conclusion, I might mention that most people out here prefer the British motor bicycle, but such are unfortunately

SCENES ON THE NORTH-WEST FRONTIER OF INDIA.

Americans is like mounting a racehorse after a draught horse.

"Of the dozens of engines, both British and American, I have taken down, fully two-thirds suffer from the gudgeon pin being loose in the piston. The result of this is scored cylinders. Piston rings are too narrow for their grooves, and the ends of the step cut rings always disappear. Small end bushes are often loose in the connecting rod, and the rollers of big ends are worn into flats. Valves are always badly pocketed, and the stems worn on one side.

not always obtainable, and the Indian and Harley-Davidson have got a big hold. The British manufacturers will have to do something soon if they intend to get a hold on the market in the near future. It is a significant fact that almost any three-year-old English motor bicycle in moderately good condition will fetch more than a similar machine would cost new at the present time."

(Left) Camel convoys, sometimes numbering 200 animals, are frequently met with in the Frontier district.

(Right) On the top of the Kohat Pass—a climb of 1,100 feet in seven miles.

(Bottom) The summit of the Kohat Pass is reached by a road well graded but full of acute hairpin bends—a hill testing the ability of the rider more than the machine.

OVERSEAS SECTION

A Commentary based upon Practical Experience and a Study of Overseas Opinions.

Loading Up the Handle-bars.

It is noticeable that, while American manufacturers make a special point of keeping the handle-bars clear of all accessories, British manufacturers seem to take a delight in loading up the bars with all kinds of impedimenta—or, at any rate, forcing the owner of the machine to do so. This is a strong point in favour of the Americans, and every Overseas rider knows the nuisances that constantly crop up in the way of handle-bar fittings working loose. When the road conditions are really bad the bars are subjected to a good deal of jolting, which is rendered worse by the necessity for fairly stiff fork springs on Overseas mounts.

This loading up of the bars is a bad principle. In the case of a heavy sidecar machine it does not matter so much from a mechanical point of view, but it is calculated to upset the nicety of steering of a solo mount, besides subjecting the fittings themselves to a strenuous time.

The heavy speedometer, at least, might profitably occupy the position favoured by the Americans, namely, the top bar, and be driven from the rear wheel of the machine. In this position it is better insulated, and the distribution of weight is more as it should be. The road clearer might occupy the same position, as this top-heavy fitting is a chronic offender on the bars. The lamp must follow the steering head, and is not generally a cause of much trouble on the bars; also, since electric lighting is in the stages of rapid development, we can look forward to the weight of this accessory being much reduced.

The loading up of the handle-bars is a thing British makers who are interested in the Overseas market should avoid, or, at any rate, if we are to carry most of our accessories on the bars, let us have brazed lug attachments, so that when once fixed they remain there for good.

Fully-equipped Machines.

No one is better able to choose the accessories than the maker, and when a machine is turned out fully equipped proper provision can be made for the attachment of these accessories. But there are difficulties in the way. One rider states that half the fun of the game is lost unless a speedometer be used; another denounces this accessory as a useless extravagance. A speedometer is doubtless a valuable accessory to the systematic rider, but the fact remains that many do not require it. Similarly one rider puts his faith in one type of lamp and another in a different kind, so that it is an impossible problem for a manufacturer to turn out a fully-equipped machine that will meet the approval of all.

A good plan has been adopted by the Enfield Company—that of turning out two models, the one minus accessories and the other fully equipped.

The system of a fully-equipped model gives the makers an opportunity not only of employing the most suitable accessories, but of fixing them in the best way and in the best positions.

Weak Points. REAR stands, rear carriers, and mudguards still persist in breaking or dropping to bits under really severe conditions, and there is need for something in the way of a general revision if these items are to hold together indefinitely on military and Overseas machines. In some cases the carrier is dependent on the mudguard for the retention of its vertical position, which is quite wrong. The carrier should be a self-supporting structure, tending to strengthen and support the mudguard rather than the reverse.

Rear stands are not sufficiently strong, are made of the wrong material, and the stop is generally too near to the centre on which the stand pivots. The result is that when the machine, possibly facing uphill, is placed on its stand, the latter is slowly but surely bent at a point adjacent to the stop, till finally it gives way. The American military machines are provided with forged channel iron stands, which is a far more sensible plan, and might be extended to the rear carrier.

It is the excessive vibration which brings about the destruction of carriers and rear wheel mudguards. The front wheel gets less of it, since it does not follow the inequalities of the road so violently as does the back. It is consequently only a matter of time before the rear guard starts to give trouble, and, instead of being called upon to help support the carrier and stand, it should be supported by them.

Springing the Sidecar Wheel.

TAKING it as admitted that some yield is necessary in sidecars, we must then decide whether this be allowed for in the chassis design by the employment of curved tubes or whether the chassis be built on correct straight tube lines and insulated from the road by springing the wheel. It need hardly be pointed out which appears to be the better engineering principle. If triangular-straight tube design be employed the chassis can be constructed more lightly than if ordinary bedstead principles be followed, and by relieving both frames of intermediate breaking strains and shocks a further all-round reduction of weight would be permissible. Quite apart from this, a sidecar having an effective spring wheel is infinitely more comfortable than one solely dependent on the tyre for absorbing

Overseas Section.—

road shock; indeed, the sidecar is the only self-propelled road vehicle designed for more than one rider that is dependent on such slender-provisions, albeit one of the fastest.

Quite apart from the questions of strength and comfort, the springing of the sidecar wheel would permit the convenience of a strong and roomy luggage grid and spare wheel carrier riding quite independently of the sidecar body. Unsprung luggage grids are

practically useless, and those attached to the body possess the disadvantage that arises from the springing of the body being unadjustable. Thus, with the grid fully loaded, springing designed to give maximum comfort under the normal conditions when only a passenger is carried is insufficiently stiff and *vice versa*.

It is sincerely to be hoped that sidecar manufacturers will give this question of springing their careful attention.

Despatch riders attached to a motor machine gun battery with their Triumph W.D. mounts in the hills of Samaria.

A Selection of Letters from Readers scattered all over the World.

British Motor Cycles Overseas.

A Canadian correspondent who is anxious to place British machines on the Canadian market writes: "I may say there is an ever-growing demand for motor cycles in Canada, and that the British machine is practically unknown. It is now, however, receiving more attention through the good reports of returned soldiers, who are loud in their praise of certain British makes. It is now six years since I left London to enter commercial life in Canada, and, undoubtedly, there has never been a period more favourable for the placing of British goods on the Canadian market than at present, with so many Canadian-born sons returning full of admiration for the Old Country and home products. As you are no doubt aware, there are no motor cycles built in Canada, America supplying the demands—a state of affairs which should not exist. With the preferential tariff and cheaper labour at home, the British-built machines ought to control the market here from Halifax to Vancouver."

An Ideal for India.

"SIND," India, writes: "I should be glad of information as to whether any make of motor cycle and sidecar combines all the requirements given below, which I consider essential to make motor cycling a success on our local roads. I have experimented with a $\frac{3}{4}$ h.p. Rudge-Multi, which has behaved wonderfully under impossible conditions, but it is held up by the worst roads.

"The roads are mere tracks, for the most part of hard clay full of holes, and with long stretches of soft sand.

"In places the roads are often flooded for long distances with water, and great power is required to plough through the thick sticky mud. It is never advisable to exceed 25 m.p.h., but it is frequently necessary to crawl for a mile at a time through deep holes at a speed of 5 m.p.h., and to do this without konking out the engine must be of fairly high power, and must be capable of running in the lowest gear for long periods.

"*Power.*—For machine with heavily loaded sidecar at least 6 h.p. is wanted, with a three or four-speed gear of substantial type, and with the lowest gear about 20 to 1. For preference, owing to its simplicity, a single-cylinder engine is preferred. The 5-6 h.p. Rudge should do well.

"*Ground Clearance.*—Nothing less than 8 in., and more if possible. This is not only for the machine but for the sidecar chassis.

"*Mudguards* with big enough clearance not to choke with the awful mud we have here.

"*Chain drive* or shaft drive essential. I find a belt takes one to the deepest part of the water, and then fails to grip, and leaves one stranded to get out as best one may.

"*Tyres.*—Certainly 28 in. x 3 in. on all three wheels, with interchangeable wheels. Punctures are frequent owing to the many acacia thorns, and it is advisable to have tyres that can be removed to repair punctures, easily and single-handed.

"The soft sand soon pulls the tyre round against the ordinary security bolt, and I have fitted 3 in. bolts to my wheels—five in each.

"*Sidecar.*—A roomy sidecar without fancy fittings preferable, and it is important that it should be fitted with a strong luggage carrier of large capacity.

"Other fittings advised are Rudge stand, powerful lamps, carburetter which will use paraffin, strongly sprung forks, and perhaps a spring frame."

Continental Desiderata.

A French rider, R. LEXE, Armée Française, says: "I would like to point out that the 4 h.p. standard type of English single-cylinder engine is the only engine which up to now has been made absolutely reliable and foolproof. With the twin one is continually bothered with the unequal oiling, unequal spring tension and valve clearance, unequal spark, air leaks, etc. What we want are rather improvements in frame design, better protection against mud and grit in the various bearings and spring forks."

SPECIAL FEATURES

MAGNETO DRIVE.

Anticipation.

A blue patch in the sky is sufficient to set one thinking of the joys of the wheel.

Motor Import Duty.

The gross amount received from the duties imposed on the import of motor cars, motor cycles, and parts during 1918 was £271,469, as compared with £288,347 in 1917 and £475,200 in 1916.

The Burney Brothers.

Capt. E. A. Burney, R.A.S.C. and Lt. C. S. Burney, R.E., are no longer connected with Messrs. Burney and Blackburne, Ltd., the makers of Blackburne engines. These well-known riders are forming a company composed of ex-officers and men of H.M. Forces who are expert engineers to open a motor agency in Scotland.

Motor Cycles in Canadian Police.

Montreal now boasts of the largest motor cycle police squad in Canada. It was only recently that the motor cycle was adopted by the Montreal authorities. The fleet now includes fifteen Henderons and twenty-five Harley-Davidsons; while the Toronto police department has a large fleet of motor cycles, including Triumphs.

The Industrial Reconstruction Council.

The third lecture of the series arranged by the Industrial Reconstruction Council will be held in the Saddlers' Hall, Cheap-side, E.C.2, on Wednesday, February 5th. The chair will be taken at 4.30 by the Right Rev. the Lord Bishop of London, and a lecture, entitled "The Industrial Awakening," will be delivered by Mr. Ernest J. P. Benn, chairman of the Council. Applications for tickets should be made to the Secretary, I.R.C., 2 and 4, Tudor Street, E.C.4.

The British Overseas Market.

A correspondent from Lagos, West Africa, who is an enthusiastic rider, writes: "I have your interesting paper sent out every mail, and find it most useful and instructive, and should like to point out, with regard to the controversy 'British v. American machines,' that our manufacturers will have to wake up now, otherwise the colonial market will be lost to them. The Americans have 'got in,' and undoubtedly turn out a much more suitable motor cycle for colonial work than the British."

Greetings from Overseas.

We have received a Christmas greeting card from Lt.-Col. S. W. Carty, M.C., R.A.S.C., who is now in Mesopotamia. Lt.-Col. Carty will be remembered as a prominent member of the Newcastle and Mersey Motor Clubs.

E. African Campaign.

The South African D.R.'s who were with the Forces operating in East Africa against the Germans have now returned home, but the D.R.'s from Great Britain are still "up country"—in Portuguese East Africa in fact—where they are busy "clearing up."

Spring and Semi-spring Frames.

It is obvious that the rigid frame with conventional saddle is regarded as out of date by a large number of motor cyclists. In the "Which Type" referendum the voting on these points showed that the ordinary type saddle was specified by a smaller number of readers than those who voted for spring frames. Rigid frames secured 21.1% and 15.2% votes in solo and sidecar classes respectively; sprung saddle-pillar and semi-spring frames together obtained 22.8% and 19.3% in solo and sidecar groups respectively.

In Season.

Mud and rain and hard thoughts concerning mudguards.

American Motor Cycle Police.

The Detroit (Mich.) traffic police are for the third year equipped with forty-seven electrical model Henderons.

Poor Benzole.

We have heard several complaints as to the quality of benzole produced. Although in these days it is unreasonable to expect spirit of pre-war quality, it will not benefit the benzole producers in the long run to continue supplying inferior quality. Motor cyclists trying this fuel for the first time will be strongly prejudiced against benzole as a fuel. And prejudice dies hard.

The D.R.'s in Africa.

Cpl. Syd. Du Rose, writing from East Africa, says: "I still continue to receive the copies of *The Motor Cycle*, and it is a treat to receive them and read the latest motor news of Old-Blighty. B.S.A.'s are still hard at work out here. No other motor cycle could stand the thrashing that a B.S.A. gets in East Africa. It is a wonderful 'bus for rough riding."

This is not a "tester's stunt," but one of the innumerable creeks motor cyclists have to contend with in all Overseas countries. No wonder that high ground clearance is always stipulated in Overseas specifications.

The Latest Spring Frame.

The 1919 No. 7 Chater-Lea will have a spring frame.

The Inventor of the Exhaust Lifter.

We are asked to name the inventor of the exhaust valve lifter. This was Mr. A. J. Wilson, who, as a motor journalist, is known as "Faed." Incidentally, Mr. Wilson was author of the first edition of "Motor Cycles and How to Manage Them," published from these offices.

T. Silver, of Quadrant Fame.

Many readers, in company with ourselves, will be pleased to hear that Mr. Tom Silver, after having undergone a serious operation, is making satisfactory progress. We trust that the rejuvenating air of Buxton will accomplish a speedy convalescence, and that, before long, he will be again moving in Quadrant circles with all his accustomed health and strength.

For the Consideration of the Trade.

At the present time there is an undoubted demand for a two or three-speed gear which can be fitted to fairly modern $3\frac{1}{2}$ h.p. single-cylinder machines. For the next six months, and until manufacturers have got into full swing, there is plenty of work to be done by clever amateurs and motor cycle repairers in converting old single-speed machines into really satisfactory sidecar mounts.

Reviews of Design.

In this issue we include another of our reviews of current design, which have been appreciated so much by readers. This article reviews magneto drive and position. A list of previous articles is given below:

	1918
Timing Mechanism, Single-cylinder Engines	May 23
Timing Mechanism, Twin-cylinder Engines	July 11

New A.B.C. Sidecar.

Mr. Granville E. Bradshaw is reported to be busily engaged upon designing a specially light sidecar for the new 400 c.c. A.B.C. motor cycle.

A T.T. Race in 1919?

There is just a bare possibility that a T.T. race will be arranged this year. It appears that the condition of the roads in the Isle of Man at the present time, and the uncertainty as to whether they can be put into proper order in time, prevents a decision being reached. Ireland is the only alternative.

Wanted, a Modern Engineering Factory.

A prominent Midland firm of motor cycle manufacturers are experiencing such a flood of orders for new mounts, far beyond the possible output of their factory, that they are desirous of getting in touch with an engineering firm of repute, with an up-to-date plant, who wish to turn from munitions to work of this class, and who will guarantee a supply to specification, probably running into thousands of machines. We shall be pleased to facilitate communications.

Testing Norton Engines.

Mr. D. R. O'Donovan, the well-known speed specialist, is again in charge of the Norton Motors testing department, and he will be personally responsible for the riding in the firm's engine speed tests on the Brooklands track. The certificate of the Brooklands Auto Racing Club will be given with each of the special engines for T.T. and B.R.S. models, guaranteeing that the engine has exceeded 75 m.p.h. for a distance of one kilometre. We are assured that there is just sufficient of the track left with a rideable surface to enable this testing to be carried out.

**THE DISPOSAL OF
ARMY MOTOR CYCLES.**

The exposure in these pages and those of our sister journal "The Autocar" of the scandalous neglect of army motor vehicles at Kempton Park and other army supply dumps has had the desired effect.

A special Department at the new Ministry of Supply has taken over from the Surplus Government Property Disposal Board the sales management of all Government motor vehicles, and it is stated that Maj.-Gen. Sir C. R. Crofton Atkins has been appointed to take charge of the new Department.

It is said that manufacturers will be given an opportunity to repurchase machines of their own make. If they refuse to buy, or their offer is not deemed sufficiently good, the vehicles will be offered to the public.

Sales of a few machines have already taken place at Aldridges, St. Martin's Lane, a report of the first of which, together with photographs, appears on page 116.

Three-wheelers in Prospect.

More attention seems to be centred on three-wheeled vehicles for this year than has ever before been the case. We know of four firms who are considering designs for three-wheeled vehicles, and there are a great number of rumours that other prominent manufacturers are considering this type favourably.

Six Days Trial in August.

It may be taken as practically definite that an A.C.U. six days reliability trial will take place in August this year. The course suggested is a new one, and will possibly be from a centre, as in 1914. By August all manufacturers should be in a position to enter either their current or 1920 models. In either case, the importance of some strenuous test is recognised by everyone.

Precision Engines.

Precision engines for 1919 are now announced. Two models are being introduced. These are an 8 h.p. twin following the general lines of the 1915 model, but with improved and silent valve gear, new exhaust valve lifter mechanism, and roller big ends; and a $3\frac{1}{2}$ h.p. single-cylinder two-stroke of 350 c.c. capacity, with many unique features, including roller big end and main bearings, and automatic lubrication. We hope to describe both models shortly.

We are not so Militarised as the French.

Numbers of French motor cyclists were mobilised in the early days of the war, and the scheme included the calling up of machines as well as riders. These machines were requisitioned by the Government at one-third of their original value. Machines have gone up so much in value that French motor cyclists are now suggesting that they should be allowed to repurchase their machines from the State on being demobilised, and should obtain preferential treatment in the question of the price of repurchase. British despatch riders have made the same suggestion.

In spite of the thrills and excitement aviation offers, Lt. Owen Edmunds, who made the first official mail flight between London and Paris, still retains his affection for the motor cycle. His mount is a 5.6 h.p. overhead valve N.U.T.-J.A.P., with three-speed hub gear. Lt. Edmunds has made over 200 Channel flights.

The Latest Information regarding the Revival of the Various Clubs.

The Motor Cycling Club's Activities.

This year's programme will include a despatch riders' trial, the opening run, and the annual London-Edinburgh run, but further news of the club's activities will be given later.

Chester and District M.C.C.

This club has not yet been reorganised, as most of its members are still away on military duty, including the secretary, Mr. R. Dutton, who is in East Africa.

Birmingham M.C.C.

The Birmingham M.C. Club's 1919 programme promises to be a very attractive one. It is proposed that the local clubs may reopen motor cycling competitions by having an inter-club trial.

Mansfield and District M.C.C.

Energetic motor cyclists in the Mansfield district should get together to revive the local club. The late secretary, Mr. C. Evinson, of the Portland Motor Co., advises us that he will not have time to devote to it.

Dublin and District M.C.C.

Mr. W. H. Freeman is again holding office as hon. sec., and four road events for 1919 have already been decided upon. A reliability trial for the Dunlop cup will be held on Easter Monday, another trial on Whit-Monday, a twenty-fours trial at the end of June, and a two days' trial on the Saturday and Monday of August Bank Holiday.

Liverpool M.C. Redivivus.

We are pleased to note that the trustees of the Liverpool Motor Club have decided to resume activities by holding a public meeting at 7.30 p.m. on February 5th at St. George's Restaurant, Redcross Street, Liverpool. Other local clubs would do well to follow their example, as there are so many problems of vital importance to the motoring community at the present time that can be better dealt with collectively.

Portsmouth Branch of the N.M.C.F.U.

On Tuesday evening, January 21st, a very successful and well-attended meeting of the National Motor Cyclists' Fuel Union, Portsmouth Branch, was held at headquarters, "Blue Anchor Hotel," Kingston Cross. The newly elected chairman, Mr. Cheyne, spoke of the future business and social prospects of the club, the evening terminating with a smoking concert.

Essex M.C.

A meeting is to be held at the Eagle Hotel, Snaresbrook, to decide upon the future activity of the club. It is intended that a strong programme, of both sporting and social events, shall be carried out, the club being in a strong financial position. Old members and intending members should communicate with the hon. sec., D. S. Kapadia, Holme Villa, Algers Road, Loughton, Essex. The date of the meeting is not yet settled.

Bolton and District M.C.

The Bolton and District Motor Club, which, in common with other motor clubs throughout the country, was compelled to suspend its activities in the early days of the war, is to be reorganised almost immediately. The first general meeting for the new season is arranged to be held at headquarters, the Swan Hotel, Bolton, on Thursday, February 13th, at 8 p.m. prompt. Other intending members would greatly assist the secretary by paying their subscriptions to him at 215, St. George's Road, previous to the general meeting.

Bristol Wheelers Cycling Club.

A meeting of the Bristol Wheelers' Cycling Club will be held some time in February, when a programme will be arranged for the motor cycle section.

Nottingham and District M.C.C.

A most comprehensive programme has been drawn up, and motor cyclists desirous of joining should communicate with the hon. secretary, Mr. H. Weldon, at the Welbeck Hotel.

Woolwich, Plumstead, and District M.C.C.

There is a strong feeling amongst the members of the Woolwich Club that active operations should start as early as possible, and a "victory" competition is among the events being planned.

Plymouth and District M.C.C.

Secretary T. D. A. Chapman advises us that at present the majority of the Plymouth Club members are scattered all over the world in His Majesty's Forces. The revival of this club is not likely to be so soon as its ex-members would desire.

Sheffield and District N.M.C.F.U.

We hear that the Sheffield N.M.C.F.U. intends providing co-operative garages in different parts of the town for its members, built on similar principles to those described by "F.A.S." in our Reconstruction Number of January 2nd.

Despatch Riders' Club.

A club has been formed to perpetuate the comradeship of motor cyclists who have been R.E. despatch riders. Such riders are invited to communicate with the temporary hon. sec., Signal Service Despatch Riders' Club, R.E. Depot, Wellingborough.

Middlesbrough and District M.C.C.

It is intended to restart this club at an early date. A general meeting will be held about the end of February. In the meantime, Hon. Sec. Jas. Gilchrist, 3, Roman Road, N. Middlesbrough, appeals to all motor cyclists in his district to associate themselves with the club.

Cork and District M.C.C.

A general meeting for the election of officers for the coming season is fixed for February 5th. It is anticipated that a full programme of events will be possible during 1919. Two members of the club have recently appeared in the *Gazette*—Capt. J. W. Payne, of the Connaughts, has been awarded the Military Cross, and Capt. W. J. Morrogh, M.C., of the Northumberland Fusiliers, the Croix de Guerre. Capt. L. D. Humphreys, the first Cork motor cyclist to join up, was taken prisoner in the first months of the war, and has now arrived home. The hon. sec. of the Cork M.C.C. is Mr. Ronald S. Russell, 4, Prince's Street, Cork.

Auto Cycle Union.

At a meeting held in London last week it was decided to make the subscription 10s. for all individual members. Members will henceforth be of one grade. The scheme comes into operation as and from March 1st. The arrangement will not affect those touring members who have paid their 5s. membership fee; and those who have paid a guinea will not be asked for another subscription for the next two years. Members affiliated to the A.C.U. through their local clubs are not affected by the new scheme.

The annual general meeting of the A.C.U. will be held at Birmingham on Saturday afternoon, March 22nd, and will be followed by a conference of members of affiliated clubs and local motor cyclists.

Club News.—

The British Motor Cycle Racing Club.

Old members of the B.M.C.R.C. are asked to communicate with the secretary, Mr. T. W. Loughborough, 83, Pall Mall, London, S.W.1, to join in an early effort to revive the club.

A Proposed Motor Cycle Club for Hull.

Great interest is being shown in an effort to form a motor cycle club for Hull, and local motor cyclists interested are requested to communicate with Mr. Fred Hall, 1, Margaret Street, Hull.

Wath and District M.C.C.

The Wath M.C.C. is one of the few clubs which have been able to "carry on" during the war. Secretary W. W. Evers (Sandygate) advises us that he has funds in hand, and that many members have already paid their subscriptions for 1919.

Eastern Counties M.C.

A meeting is being arranged by the hon. secretary, Mr. J. W. Percival, 5, Ruby Road, Walthamstow, in order that the Eastern Counties Motor Cycle programme may be arranged. Old members are asked to communicate with the secretary.

A Belgian Motor Cycle Club.

The Federation of Belgian Motor Cyclists is holding a preliminary meeting shortly, and every effort will be made to revive motor cycling. One of the evils the Federation is out to combat is the carrying of two enormous number plates, which Belgian motor cyclists find a great inconvenience, and every effort is being made to adopt the British system of numbering.

A SPARKING PLUG WITH DETACHABLE ELECTRODE.**The XL-ALL—A Newcomer to the Sparking Plug Industry.**

ONE of the chief faults of plugs is the difficulty in cleaning their interiors. It is not sufficient to remove the carbon "bridge" across the electrodes; a film of carbon is deposited over the whole internal faces exposed to the explosions. This can be only partially cleaned away by washing out with petrol, in even the best of plugs. In fact, many of the best plugs seem to be the worst offenders in this respect.

With these facts in mind, the XL'All Co., Ltd., of Hall Green, Birmingham, makers of the well-known XL'All saddle, have designed a plug, the first and foremost advantage of which is the ease with which it can be dismantled, the central electrode being withdrawable, and every surface needing cleaning exposed. The body of the plug is of usual dimensions and case-hardened, with four hexagonal cooling fins formed with the outer electrode out of the solid. This construction leaves a small aperture, through which the central electrode projects, thus forming the spark gap. The porcelain, in two parts, and the nickel central electrode are locked up in the one unit with a second and upper body of smaller diameter, which also has four hexagonal cooling fins, and is threaded into the lower part. The joint is made with a copper asbestos washer, thus merely making an exact replica of the ordinary plug joint with the cylinder or valve cap.

The construction of the insulating porcelains and the central electrode is particularly designed to obviate any leakage, and an extremely fine degree of accuracy in workmanship is to be maintained to ensure perfect joints and concentricity of the electrodes, thus giving an unvarying spark gap no matter how many times the plug is taken apart.

We are told that exhaustive tests have proved this plug to be remarkably efficient. It has been tried in a variety of machines, including two-strokes, big V twins, and even a works gas engine.

Although of special construction, it is to be put on the market, almost immediately, at a very reasonable price—in fact, much cheaper than many special types of plug.

**N.M.C. Fuel Union.**

A social evening of the above Union will be held in the Athenæum Room of the Royal Hotel, Derby, on Saturday, February 1st, at 7.30 p.m. An address will be given by Mr. E. S. Shrapnell-Smith, C.B.E., deputy director of Technical Investigation, H.M. Petroleum Executive.

The Cyclecar Club.

In order to restart the Cyclecar Club, a committee meeting will be held at the R.A.C., 83, Pall Mall, on Friday, February 7th, at 8 p.m. Various important matters will be discussed, including a change of title, subscription, and other proposals to be submitted to a special general meeting to be held at a subsequent date.

Ladies' Club in Coventry.

It is thought that there are sufficient lady motor cyclists in the Coventry district to form the nucleus of a ladies' club, and several keen riders of the gentler sex are desirous of forming such a club. Those interested are invited to communicate with Mrs. H. Williams, 76, Sir Thomas White's Road, Coventry.

York and District M.C.C.

Mr. G. A. Reed, 6, Blake Street, York, the captain of the club, is acting secretary *pro tem.* pending the election of officers at the general meeting, which, it is hoped, will be held at the York Station Hotel, on Wednesday, February 26th. No definite programme has been decided upon so far, but it is thought that social runs on alternate Wednesday and Saturday afternoons will be a regular feature, while several trials and hill-climbs are in contemplation. All local motor cyclists should get in touch with Mr. Reed.

LONDON'S APPROACHES.

The scheme for the construction of a new western road from London, which was on the tapis before the war, is being revived, and it is hoped that some definite decision may soon be reached. The engineering difficulties are negligible, and the question now resolves itself into one of finance and arrangements with the number of local authorities to be considered. We hope to hear more of this in the near future.

THE PETROL POSITION.

It is a relief to note that there is some prospect of improved fuel in the near future. The Government has in stock a considerable quantity of special aviation spirit, which is to be mixed with No. 3 spirit in such quantities that the mixture will represent a good petrol of No. 1 quality, which is promised at 3s. 3½d. a gallon.

Possibly the fact that it is not always possible to obtain petrol in some districts may give rise to the idea that there is still a national shortage of spirit. This is not the case, however, as local shortages are brought about by inadequate transport facilities.

B.S.A. PLANS.

In future the manufacture of B.S.A. motor cycles and bicycles will be run by a company separate from the Birmingham Small Arms Co., Ltd., which will be known as B.S.A. Cycles, Ltd. Mr. C. A. Hyde, the manager of the cycle and motor cycle departments of the parent concern, will be managing director.

Mr. Hyde is one of the best known figures in the trade, with which he has been connected for over thirty years. He invented the Hyde free wheel, which is now a universal fitment on pedal cycles. He is president of the Cycle and Motor Cycle Manufacturers' and Traders' Union, member of the Council of Federation of British Industries, member of the Executive Committee of the Association of All British Motor and Allied Manufacturers, member of the Local Advisory Committee to the Ministry of Labour, and chairman of the Executive Committee of the Engineering and National Employers' Federation (Birmingham District).

Now that the Government contracts are about to terminate, the whole of the enormous surplus factory space and plant will be adapted to the construction of cycles and motor cycles on a scale hitherto unprecedented.

W.D. Surplus Stock under the Hammer.

Last Week's Sale of Government Motor Cycles.

Some of the Scotts. These machines fetched quite good prices

THE first sale of Government motor cycles took place at Aldridges on the afternoon of the 22nd inst. Altogether nineteen machines were sold, consisting of Rudge-Whitworths, Zeniths, Rovers, and Scotts. There was a large number of bidders, consisting chiefly of dealers, but a number of young officers in khaki were conspicuous in the crowd.

Remarkably good prices were obtained; the Rudges fetched between £37 and £39. Five Zeniths were sold at an average of £42, the lowest price obtained being £39 and the highest £53. These machines were sold as being in fit condition. Unfit Rovers made from £24 to £33, while the Scotts, which were not in particularly good condition, were sold at prices ranging from £26 to £43.

Besides the lot of Government machines there were sold a 1915 $4\frac{1}{4}$ h.p. B.S.A., with sporting sidecar and disc wheels, guaranteed in working order, which fetched £74, and a Triumph combination which went at £26.

It is interesting to compare these prices with the average second-hand prices published in last week's issue, remembering that the sellers in these cases were private owners. Among the surplus machines at Kempton Park are a number of the following makes: Lea-

Francis, A.J.S., Enfield 3 and 6 h.p., Nut-Jap, Singer, Premier, Matchless, Bat, Rex, Regal, Motosacoche, Levis, P. and M., Sunbeam, and Bradbury. A large number were privately owned machines which were taken over by the Government in 1914.

(Top) A batch of Rudges and Rovers which had been renovated in Government repair shops. (Left) A mutilated Scott, which was nevertheless sold for a good price. (Right) A privately-owned $4\frac{1}{4}$ h.p. B.S.A. sidecar, which found a buyer at £74.

OPINIONS.

Notes on the Past, the Present, and the Future. By Prominent Men in the Motor Cycle Movement.

CONCLUDING SERIES:—Comments of Competition and Other Well-known Riders.

From Mr. Frank Whitworth, Prominent in the Birmingham Retail Trade, Popular Clubman, and Successful Competition Rider.

TO set down all the thoughts that occur to one relative to the "re-construction" position and future possibilities of the motor cycle would occupy more space than is at my disposal. First, as to quantities, the possibilities seem almost boundless. Why should not everyone in Great Britain have a motor bicycle—everyone between, say, the age of nine and ninety? This would enable

Mr. Frank Whitworth.

some decent-size outputs and some real quantity production. Yes, enormous expansion in quantity is the first probability that strikes one in relation to the future of motor cycling, though perhaps not to quite the extent I have suggested. Next, as to the future type, there is one point that impresses me more than any other; the type is no more fixed to-day than it was in the first and false boom of 1904, nor in the second and genuine boom of 1910. "Producers and users were, in those days, uncertain and wavering between different types of engines, transmissions, and frames, and to-day they are still as doubting and undecided. Indeed, the manufacturers are, apparently, so far as the bulk of them are concerned, feeling less decided in their steps to-day than they were in 1910.

In 1910 practically every one of the big makers who then stepped into the trade, mostly from the pedal cycle ranks, followed a certain well-known and successful lead, and produced a $3\frac{1}{2}$ h.p. single-cylinder diamond-framed machine. It is probable, if the dozen biggest makers of the years 1910 to 1914 were tabulated, it would be found that two-thirds of them produced machines of that type. The general opinion seemed then to have settled on the 500 c.c. single-cylinder as the desideratum of the motor cyclist.

Even to-day it is probable that, of the existing big makers whose names are best known to the public, the majority are still principally working upon the same lines. But I submit that the average motor cyclist and the average manufacturer are not to-day feeling even so confident of the trend of future design as in 1910.

New concerns are organising in the background, recruited from entirely different sources. For whereas the older

motor cycle firms mostly sprang from pedal cycle origin, some of these are coming from the aeroplane industry, and they approach the subject of motor cycle design from an entirely new standpoint. Their constructive ideas begin with the engine, and then work through to the suitable transmission, frame, etc.; the older school started with the bicycle, and the engine came later for adaptation to the bicycle. With the two schools competing we shall get some improved results from both, particularly in the direction of decreasing weight whilst maintaining power.

New concerns are coming, and are already making claims for the future of their new types of machines. They assert they can give increased general suitability and efficiency for the purpose for which the motor cycle is required, namely, the safe, certain, speedy, simple, comfortable, and economical transit of one or perhaps two persons from one point of the country to another.

From Mr. W. B. Gibb, the Gloucester Agent, who is perhaps better known as a Successful Competition Rider.

IF there is one point more than another which I may criticise in the present-day motor cycle, it is that of the inadequate protection from mud.

The war has certainly brought out the weak spots of the motor cycle, several of which the manufacturers have remedied—much to their credit. Happily we already see signs of improvement—in giving more clearance between wheels and mudguards, thus obviating the necessity of the rider dismounting to remove the mud with a stick from time to time.

Mr. W. B. Gibb.

Clearance, however, does not prevent the rider from being plastered from head to foot in mud, after a few miles on such roads as we have had in the last few weeks.

Many riders will agree that it would be to the mutual advantage of businessmen and the trade generally if this drawback could be remedied at an early date. The former recognise that they must arrive at their client's residence in a presentable condition. We see from time to time many home-made devices to protect the rider; but why should this be necessary? Surely manufacturers are in a better position to devise some adequate means of protection for the rider, and thus obviate the necessity to don overalls when making business calls at distances of a few miles.

Manufacturers have done well in developing the power unit during the last few years, and I, for one, feel confident they can do equally well in regard to the question of mudguarding, if they will only definitely lay themselves out to tackle this problem, that is undoubtedly requiring urgent attention.

From Mr. Hugh Mason, Winner of the 1913 Junior T.T.

FOR four years the ever-increasing demand for munitions has gradually organised rapid, accurate, and massed productive methods which were practically unknown before the war. This and the testing and treating of material, together with the extremely fine limits of tolerance in the gauging and inspection departments, must surely prove extremely beneficial and a lasting education to those called upon to resume the manufacture of motor cycles.

From the manufacture of munitions of war to motor cycle manufacture without notice (as it must be if we are to produce

for Easter) is indeed a problem of vital importance to all concerned. However, when the time comes, of one thing I am surely certain: machines may not be cheap in one way, but the motor cyclist will get better value for money than ever before, as a machine manufactured upon up-to-date methods necessitates that all parts must be interchangeable to the last degree. Again, all working parts, including nuts, etc., must be hardened, and suitable set spanners supplied; also larger tyres, more efficient mudguarding, dynamo lighting, automatic and semi-automatic lubrication will be required, and the whole machine made generally more durable throughout.

I am of the opinion that fewer models will be manufactured, possibly only two, viz., lightweight solo and sidecar combination. The latter calls for the more improvement, inasmuch as drivers will require much more protection than formerly, or they may quickly become light car owners. Open frame ladies' machines will not be demanded, as the fair sex, having responded to the nation's call, have consequently become more sporting; and, suitably clad, they will prefer the standard and more rigid type of frame, particularly as this standpoint will enable them to use any make or model, solo or sidecar, which comes their way.

Mr. Hugh Mason

Opinions.—

From Mr. Fred Dover, the Coast Rider, of Sheffield.

DURING the last three years I have been driving an American 7 h.p. twin three-speed countershaft model, and have always been able, up to the last few months, to get any part I required. Although the machine has its drawbacks, I have every reason to be well satisfied with it.

I consider that unless manufacturers pay great attention to working on standard lines, and to secure the easy purchase of spare parts (and the said spares to fit when secured), they will be left behind.

With regard to future competitions, I think from a sporting point of view they will be uninteresting, on account of being largely technical. The present-day

Mr. Fred Dover.

machine and rider can do anything in the way of running to time and climbing hills, and, in my opinion, the popularity of the old events was due to the sporting element. What the machine of the future will be depends upon the requirements of the rider.

For dodging about town on pleasure or business without luggage, it seems to me a 2½ h.p. two-stroke two-speed countershaft model fills the bill. For solo distance riding with a small amount of luggage and a sidecar attached occasionally, a 3½ h.p. single three-speed countershaft chain-cum-belt is my fancy. For touring with passenger and luggage for two, I want a 7 h.p. three-speed countershaft, 28in. wheels, 3in. tyres, all-chain jigger; spring frames on all models. I should vote for 28in. wheels on all models also; but, being of short stature myself, I think 26×2½in. for solo riding would be better.

Manufacturers, in their own interests, should do all they can to improve and perfect the "sundry" side of motor cycling, including perfect lighting arrangements, cheap fuel, and prompt attention to spares.

From Mr. Harold Weldon, Hon. Secretary, Nottingham and District M.C.C.

HOWEVER keen we may be on British motor cycles, I think we must admit that in design our best makes are not progressing as they should. Compare any British car with the best motor cycle made, and it becomes evident at once what a long way behind is the motor cycle. Why should it be? We did not wait for the Americans to show us how to fit four-cylinder engines in our cars; why should we wait for them to show that they are desirable in motor cycles? Why did we let them get on the market with all-chain drives, what time we were still hanging on to belts? Not because American engineers are more clever than ours. No! Then it must be our manufacturers who are to blame.

If we in England can produce the finest cars in the world, why cannot we produce the finest motor cycles?

Is there any reason why we should not have four-cylinder, three-speed, spring-frame, detachable wheeled machines, with automatic carburetter and lubrication the same as we expect and get on any car? I plump for four cylinders, because it has been proved in the car world that the four makes a better all-round car than does a twin engine; it is a better wearing car, and no more trouble to keep in order.

The same thing will happen with motor cycles, and, although I believe in British goods for Britons, I submit that there is no sweeter running motor cycle made than the American Henderson. Our V twins will not bear comparison with it either for smooth running or for life of bearings—big-ends especially. A big, easy compression, long-stroke flat twin might run it close, but there isn't one. Our frames, with one or two exceptions, are the same as they were when I first started riding in 1908. Spring frames we must have. Rigid frames are no use to our cousins in the Colonies, and they would like to use British machines if possible.

We motor cyclists who ride to business every day are watching the cycle car movement closely, but cycle cars must be built on sturdy, simple lines like the Morgan. In 1913 I owned a G.W.K., which I ran for 18,000 miles, and the only times I had trouble with the friction drive was when I had to start away up hill. Now if this car had been half the weight (mine weighed 15 cwt. unladen) I do not think it would be stuck anywhere. I am now running a Morgan and an 8 h.p. Zenith, and have nothing but praise for both of them.

From Lt. Francis A. McNab, R.N.V.R., of Brooklands Fame.

MAY I, in view of the tendency of modern designers to increase both cost and complication (i.e., four-speed gears, spring frames, kick-starters, clutches, extra large and expensive tyres, etc.), make a plea for a sporting, simple, and moderate-priced type of machine? From personal experience I feel convinced that this constitutes the kind of machine that will appeal to a large section of service men on their return to civil life.

Lt. F. A. McNab, R.N.R.

The specifications of the type of motor bicycle I have in view would be somewhat on the following lines:

Engine, 500 c.c., single-cylinder, with decompressor. A simple, light countershaft two-speed gear box, with chain-cum-belt drive. No clutch or kick starter, the decompressor on a well-tuned engine eliminating the necessity for these. The gear change should be foot-operated, leaving both hands free for starting and control.

I am sure that this type of machine has many advantages, both from the manufacturers' and the riders' point of view. From the standpoint of the former, simplicity in construction means few complicated (and therefore expensive) parts to be made, resulting in a quick change-over and early delivery.

I also maintain that the fast and handy type, easy to keep in tip-top tune (and, incidentally, quite capable of taking a light sidecar on any ordinary road), is what the really sporting rider wants.

We are none of us likely to be blessed with too much £ s. d. for some time to come; therefore, its price should make this machine the choice of many.

May I, in conclusion, offer my congratulations on the splendid way *The Motor Cycle* has kept its high standard of interest throughout the war. I wish it the best of luck and a speedy return to the good old times of plenty of petrol.

From Sec.-Lt. B. Alan Hill, Competition Rider and Journalist.

IN my opinion, future motor cycles will eventually be divided into three distinct classes—i.e., the commercial, the luxury, and the sporting types. The manufacturer who wishes to capture all three classes of trade, and especially the first two named, will undoubtedly have much heavy spade work to accomplish. I expect the ultimate outcome will be that few will tackle the problems offered by all three classes, and each manufacturer will specialise in the particular class he favours, in the same way as is commonly done in the car trade at the present time.

As far as the sporting machine is concerned, I fancy the present type of motor cycle already caters pretty well for all tastes from a sporting point of

view alone, and it seems doubtful whether future designs could possibly improve to any great extent on present types. In pre-war days this type of rider was undoubtedly in the majority, this probably being due chiefly to the facts that the trade did not cater sufficiently for the business man or the man who desired comfortable and luxurious travel, also the fact that the public had not learned the hard lesson of war, i.e., economy.

Before economy became a consideration to all, the business and trades men resorted naturally to the cheap and efficient Ford, while the man who required a machine for comfortable travel usually sported the comfortable high or medium-priced car. Now is the time, while economy is still a necessity, for the motor cycle industry to strike a decisive blow and prove that a motor cycle can be produced that can not only compete with cars on their own ground, but beat them on the score of economy and low original cost.

Sec.-Lt. B. Alan Hill.

Opinions.—

Undoubtedly the type which has so far received the least attention, and upon which the trade should concentrate, is the commercial machine, for which there is, even now, a big demand, although the available types are only makeshifts, while if a proper commercial machine be produced, the demand, I am sure, will be enormous. I suggest that the following features should be the chief aim of the manufacturer.

Simplicity of construction; accessibility of all parts; suitability for either solo or sidecar use; adequate protection from mud and damp for all moving parts; foolproof and simple control, and simplicity of adjustment; automatic or mechanical means for lubrication of all parts; protection for the rider from mud and dirt; quantity production; standardisation of all parts; and, above all, production at a price which will absolutely defy competition by the cheap cars which have monopolised the market up to now for this class of work. This type of machine should appeal to the tradesman for goods delivery.

From Mr. R. J. Mecredy, Editor of "The Motor News."

ALTHOUGH I have possessed many motor cycles, the only one that appealed to me was a 1900 1½ h.p. Phoenix.

It was built on the lines of the pedal cycle, and the little engine was secured in the angle of the frame between the diagonal and the tube running between the bottom bracket and the head. The drive was by belt, and the usual cranks and pedals were fitted, and I had a three-speed pedalling gear installed in the back hub, with a high speed of 100in. I have been an ardent pedal cyclist since the year 1879, and always thoroughly en-

Mr. R. J. Mecredy.

joyed the mere act of self-propulsion, for I am one of those energetic people whose happiness depends, mostly, on energetic exertion, though I must admit that the climbing of steep mountain passes, either pedalling or pushing my bicycle, often proved irksome.

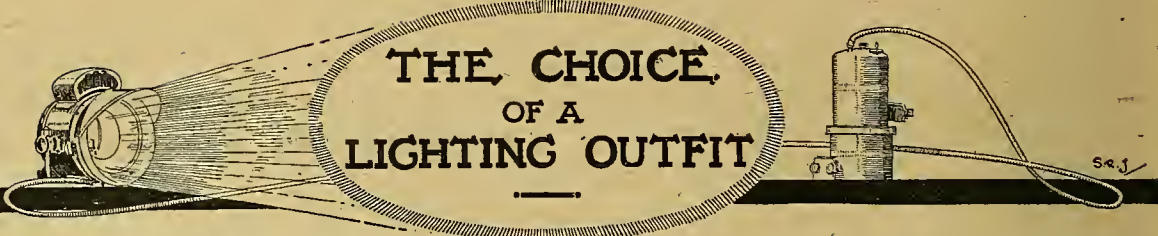

The Phoenix solved the problem. The starting of the engine on low or second speed was easy and rapid. Once under way I switched in the 100in. pedalling gear and moderated my pedalling just short of the point when perspiration becomes unpleasant; and when I hankered after a free-wheel downhill or on the level, I could, if so disposed, cease pedalling and leave to the engine any work there was to do. Much of my riding was done amongst the Wicklow mountains, and never once did I get stalled. Quite moderate pedalling kept the little engine revving at its most efficient speed, and I never knew it overheat.

As a matter of fact, this natty little combination embodied, from my point of view, the best features of both the push bicycle and the motor bicycle.

THE BUYERS' GUIDE.

Current Prices and Delivery Dates for 1919 Motor Cycles.

Make.	H.P.	Particulars in Brief.	Price.	Delivery.	Make.	H.P.	Particulars in Brief.	Price.	Delivery.

THE CHOICE OF A LIGHTING OUTFIT

A Survey of the Various Types and the Principles on which they Work.

THE "Which Type" referendum brings up the question of lighting sets for the motor cycle, both solo and sidecar outfits. Now this is one of the details which concern the whole of the motor cycling fraternity very closely. Yet many do not know the elementary principles and construction of the type

(Left) Sectional view of an ordinary type of generator.
(Right) The Low generator in section.

they advocate. In the following notes a survey of the various types of lighting sets is given which may be helpful.

Gas Systems.

Perhaps the lighting apparatus most familiar to the motor cyclist is the acetylene lamp with the separate gas generator. Of this lamp there are many types, but the principle remains the same in each. The simplest generator, one familiar to all who have used acetylene lamps, is constructed generally as shown in the first sketch. The drawing is practically self-explanatory. The apparatus consists of a container for carbide and a water reservoir, the water supply being controlled by valve operated from above as shown. The carbide is kept in a compact mass, by a spring-loaded plate. The gas is generated by the chemical action of the water on the carbide, and passes through holes in this plate, and through holes in the "floor" of a superimposed chamber filled with asbestos wool, or similar substance. There it is cooled and filtered to remove any solid matter or steam likely to be in suspension. From the chamber it goes to the outlet *via* a brass tube passing through the water container, and so to the lamp.

Various modifications of and improvements on this simple type have been adopted by makers at different

times, such as shaking grids in which the carbide is held in a wire basket. In this device the vibration of the machine shakes the used and powdered carbide into the well of the vessel, leaving the rest unclogged.

Another type of generator is the "Low," which is illustrated diagrammatically. The body is made of steel lined with a porous substance, such as plaster of Paris. The carbide is placed in a container in the bottom of the body, and the water reservoir is attached to the cover. The generator is operated by unscrewing the upper milled nut which opens the water valve. The gas generated gradually raises the internal pressure and may be released for use by opening the needle valve on the outlet pipe. If this is not done the pressure gradually rises to about 30 lb. per square inch. At this point the pressure, acting through the small orifice leading to the chamber in the lid, operates the small rubber valve which closes the water supply valve, thus stopping any further generation of gas. The object of the porous lining is to absorb some of the gas under pressure, which it releases when the pressure drops. Great economy is possible by the use of this type of generator.

A very clean and handy method of utilising acetylene gas is to compress it in cylinders, so that all the rider has to do is to connect up a fresh cylinder bought ready charged, as each becomes empty, and there is no waste of time and no messy handling of carbide, etc. As there is undoubtedly danger in the carrying of this gas under pressure, various methods have been tried of rendering it safe, and the most successful so far is that known as "dissolved acetylene." The gas is pumped into cylinders, which hold about five cubic feet, and the lamps are fed through a pressure-reducing valve. This system, though perhaps expensive in first cost, is admirable from every point of view, the only difficulties being those of distribution, which, of course, are not insurmountable.

The "service" in connection with its distribution and the changing of cylinders is properly organised. The cylinders

must be as easily obtainable as petrol used to be—at every repair shop and every other ironmongers.

This practically covers the field as regards gas lighting, which has many good points and many objectionable ones. Carbide is not the most pleasant stuff

A compact dissolved acetylene set, the cylinder being carried on a bracket fixed to the steering head.

The Choice of a Lighting Outfit.—

to handle, particularly in conjunction with water, and with the motor cycle lighting set this has frequently to be done at the most awkward times in the dark and the rain!

Electric Systems.

Electric lighting has made great strides during the past few years, both as regards reliability and portability. Where dynamo-lighting outfits have been used for the motor cycle they have generally been confined to the big sidecar outfits, and altogether too cumbersome and unsuitable for solo use. Now, however, the outlook is more favourable and solo outfits should soon become a standard. Besides the dynamo, of course, there are many other systems, such as the flywheel magneto lighting, accumulators, dry batteries, and the American dynamo lighting sets.

An example of the fly-wheel magneto type was illustrated in *The Motor Cycle* of July 18th, 1918, with a description of the Johnson motor wheel. This is naturally a very simple type, yet it must, of necessity, be designed and built with the engine.

Accumulators are suitable for either solo or sidecar machines, but for the former the difficulty is storage, which must be neat and substantial to protect the accumulator from possible damage, either by direct injury or vibration, etc. Accumulators are useful where there are facilities for recharging, but they require a certain amount of care in use and may be easily damaged in the hands of a novice.

For those who do not understand the action of the accumulator it may be stated briefly as follows:

An accumulator is a secondary battery, that is, its power of giving out a current is the result of having had a current forced through it from some primary source of supply. The chief advantage in a secondary

battery is that it can be discharged and recharged time after time. The action of nearly all accumulators depends on the fact that if two plates—one of lead and one of lead peroxide—are immersed in sulphuric acid, and an external circuit completed between them, a current will flow through

the acid to the peroxide plate, and thence through the external circuit back to the lead plate. In practice each cell may contain one peroxide or "positive" plate sandwiched between two lead or "negative" plates. Each cell gives out about two volts, so that the usual double cell has a 4-volt current, which is quite good for motor cycle lighting work. A convenient size for solo work would be a 20 ampère hour with two lamps, and for sidecar with three lamps a 40 ampère hour.

The accumulator may be perfect in design and construction, but it is always subject to diminution in capacity by neglect on the part of the user. The fact that attention only is demanded at rare intervals is one of the reasons why electric systems are liable to be neglected. As regards the lamps, a 12 c.p. bulb is ample for the head light, and 2 c.p. for the tail and sidecar lamps.

A good dry battery finds favour with many solo riders on account of its cleanliness and handiness, and an ordinary 4-volt battery should give a good light for about seventy hours, or on an average six months' use. A separate

battery is advisable for each lamp.

The combined dynamo magneto is used on a number of American machines. This system comprises a dynamo and coil which are fitted in place of the usual magneto. The coil converts the low-tension current to high-tension for the ignition, the low-tension direct current charges the storage battery, operates the horn, and lights the lamps. Since the British magneto industry has grown so enormously during the war, it is not likely that this type will be adopted as a standard by many makers in this country.

Another method of obtaining electric light sufficient for two lamps is the F.R.S. system, using the standard magneto to produce the current. With this system it is necessary to carry an accumulator for use when the machine is stationary.

Parts of the F.R.S. dynamo set. -The ring at the right is attached to the rear wheel and forms the driving disc.

The fly-wheel type of generator, which also provides the current for ignition purposes.

The disposition and wiring of a dynamo-magneto lighting plant on a solo machine

LETTERS TO

THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

SUITABLE GEAR RATIOS.

Sir,—With reference to the article, "Gear Ratios on a Solo Machine," on page 81 of your issue of Thursday, January 16th, might we point out that the Rudge Multi infinitely variable gear gives $3\frac{1}{2}$ to 1 on top (which, apparently, is higher than any gear obtained with the gear boxes mentioned in your article), combined with a low gear of $6\frac{1}{4}$ to 1, which also appears to be what your contributor desires for solo riding? No doubt it was this happy combination which enabled Mr. C. G. Pullin to win the last T.T. Race ridden in the Isle of Man in 1914.

RUDGE-WHITWORTH, LTD.

CONES WORKING LOOSE.

Sir,—I notice in your issue of January 2nd one of your correspondents complains of his cones working loose. I presume, after carefully reading his letter, that his hubs are disc-adjusting, as used on our P. and M. machines. In these the cone is not adjustable, but the cup, which screws into the hub shell and the adjusting side, is fixed by a locking ring or nut. What usually causes this to come undone is the wheel being put in the wrong way about. If the adjusting side is left-hand thread, the wheel should be put in with adjusting side on the left side of the machine, and, if right hand, to the right side of the machine. Trusting this will be of some use,

W.E.T. (R.A.F., D.R.).

DIRECT BELT DRIVE.

Sir,—May I express my appreciation of *The Motor Cycle*, and especially of the exceedingly interesting and most helpful "Occasional Comments" of "Ixion"? It is good to see *The Motor Cycle* of last week, which is so much more like that of old days, both in bulk and general character.

It may interest you to know that I am a schoolmaster, and find my motor cycle of great use in my work, or, rather, in getting to and from my work.

I wish I could see more said in favour of direct belt drive. I still maintain that it is an ideal drive on a big twin, and most economical. There is no need to suffer from belt slip, even in a deluge of rain. Again and again I have come 150 miles through continuous rain on an 8 b.p. Matchless without the slightest trouble from belt. Please say a word or two in its favour occasionally, or ask "Ixion" to do so.

E. B. HALL.

ROAD REPAIRS.

Sir,—I am an old-time reader of *The Motor Cycle*, and I should like to voice my opinion on the article, "The Problem of the Roads."

The writer states: "In France there is a huge organisation of labour battalions under our most famous road experts, who have been doing little else than repairing the highways of France for the use of our victorious armies. It would therefore not be difficult to bring this organisation over here." Well, that sounds all right on paper, but is the writer aware of what sort of men compose these different battalions? Is he aware of the fact that there are a good percentage of "1914 Mons men" among them, who have been taken out of the firing line during the last few months of war owing to their being "military war-worn and to debility"? I for one, and many others of my company, have been out here since August, 1914, with unbroken Active Service, and, having done our share of the struggle, it is up to the authorities to release us. We have been treated quite badly enough without having the agony piled on, and we have no desire to soldier on. If there is any shortage of labour at home for road repairing, why not

engage the "Conchies" or prisoners of war, and, if need be, some of those fellows who evaded military service in different Government offices? I am sure they would be better suited for the job than some of us. Remember that the majority of the motoring men are still out here, and when we read such articles as I have referred to it makes one's blood boil.

(LATE) CORPORAL R.F.A.

B.E.F.

PETROL FEED PIPES.

Sir,—As an amateur motor cyclist, may I trespass on your space to ask a question which has puzzled me?

Why are the majority of carburetters fed by a pipe coming to the bottom of the float chamber, and not the top? I have used both. With the ordinary pattern I had trouble due to dirt in the pipe and round the needle; and a bent petrol pipe is not easy to clean at the best of times.

Now, the other day I thought my other carburetter (a B.S.A.) might need cleaning. Imagine my surprise when I found a hard, thick layer of dirt in the float chamber, which amounted to half an eggcupful, enough to block a pipe a dozen times. I never had noticed any trouble before cleaning, and there was no improvement afterwards, but I venture to suggest I should have been stopped a dozen times with my old machine.

Now, sir, surely there must be some advantage in the more usual type, but it is not simplicity, for all mechanism to depress the needle is done away with, and as the float rises it carries the needle with it.

Why, therefore, I ask, are the majority of carburetters fed from below, when the overhead form seems so much more simple and far less likely to cause trouble?

N. H. KETTLEWELL.

THE COMMUNAL GARAGE.

Sir,—I was interested in your article in January 2nd issue on the garage problem. It is a problem, and one that can only be overcome satisfactorily by motor cyclists clubbing together and building their own sheds. I have often wondered why blocks of lock-up sheds have not been built in new districts. Before the war a friend of mine put up two houses, which cost, with land, £600. His revenue from his capital outlay was £50 gross. I tried to persuade him at the time to use the land for a block of lock-up garages, for which he obtained a builders' estimate, which would have brought up the capital outlay to the same amount, £600 for forty sheds, which, rented at one shilling per week each, would have brought in a revenue of twice the amount he received from the houses.

The reason he did not decide to build the garages was his lack of faith in sufficient motorists in the district to rent the sheds. Probably he was right in his particular district, but there are many localities where it would pay the builder to put up a block of garages and bring in a handsome return on the outlay, and at the same time afford very cheap motor accommodation.

I think it is possible for such blocks of garages to be built so that they could be rented at about one shilling per week for a shed large enough to accommodate a sidecar. If two solo riders joined company their garage problem would be solved at a cost of sixpence each per week.

It seems absurdly low, of course, but let anyone look at a house and garden, renting at, say, ten shillings per week; let him calculate how many motor cycles could be stored on the same area—surely it would find floor space for more than ten machines. And surely the building to accommodate them would not cost the same as the five or six-roomed house?

CO-OPERATIVE.

PRICES.

Sir,—I made enquiries a few days ago for a motor cycle chain of a certain make. The enquiry was made at four different houses, and I received four different prices, viz., 8s., 5s., 4s. 6d., and 4s. per foot. This is not encouraging to the motor cyclist, and the above speaks for itself. Cannot the manufacturers in the interest of motorists fix prices reasonably, and advertise them?

Ilford.

NOT CAUGHT.

Sir,—In your table of the different makes and their programmes, I notice that you have put down the price of our machines as £70, definite. On reference to our letter to you of January 3rd, it would appear that we have not made it sufficiently clear that this price of £70 is purely provisional. We have only said we are hoping to market the machine at £70, but it may be more. We hope to be making a definite announcement within the next three weeks. We are most anxious not to mislead our market, and when we are unable to state a thing definitely we would much rather leave it clearly an open question.

THE SOPWITH AVIATION CO., LTD.

ALAN R. FENN.

Sir,—I note in your issue of last week the letter of "H.L.I.," in which he refers to my answer to "Disgusted," which, he states, explains nothing. May I again trespass on your valuable space to inform "H.L.I." that I did not attempt to explain altogether the rise in prices? That I leave to the manufacturer. What I did do was to protest against the attitude of "Disgusted," who singled out one particular make because its sponsors had the courage to publish their price, which, at the most, is only temporary, and subject to a decline when the cost of raw material permits it.

I pointed out to "Disgusted" that the firm to which he referred had not advanced this particular model any more than those of other first-class makes; and I am now indebted to the Editor of this popular journal for his publication last week of "The Buyers' Guide," which alone confirms my remarks in my answer to "Disgusted."

The firm referred to is one of the most conscientious in the trade; in fact, I consider that the British manufacturers are a conscientious body of men, who command the goodwill of the world, particularly in the motor trade, and as an American citizen I have no hesitation in stating that if the British motor cycle trade were permitted to have a footing in the American market they would be second to none, and capable of holding their own, for I consider the British machine the best, and second to none in point of workmanship, reliability, and practical engineering.

Another point I raise for "H.L.I." to consider is the present second-hand prices. I have taken a few from last week's issue of advertisements of leading agents as follows: 1916 8 h.p. Sunbeam, £160; 1916 Enfield, 6 h.p., £105; 1916 A.J.S., 6 h.p., £100; 1917 Harley-Davidson, £120; a 1916 Triumph solo, £80; and a Douglas solo, £70. This selection of second-hand mounts, I contend, speaks for itself when a comparison is drawn in the price of brand new models, up to date and embodying improvements which enhance their value, comfort, and convenience on the road, such as are now being produced.

"H.L.I." claims to have had a review of stocks of new motor cycles held by the leading agents. So have I, and in my opinion these stocks are hypothetical and on paper only; but I cannot agree with him as to the price being fixed since December 5th, 1918. He must bear in mind that, apart from raw materials, there is yet considerable difficulty in obtaining tyres, chains, balls, and other necessary things, which are still advancing in price, and which manufacturers cannot control. This alone justifies the increases to which "H.L.I." refers between the dates mentioned.

JEFFERSON J. MOORE.

LEAKAGE OF MAGNETISM.

Sir,—Re the loss of magnetism in Dixie magnetos. I see Mr. Chapman advises fitting either a brass sprocket or, better still, a steel sprocket with a brass centre. I own a 1916 B.S.A. with Dixie magneto; and not liking the idea of a brass sprocket, I had my steel sprocket bored out and a brass centre driven in. The result was exactly as before. Immediately the sprocket was placed on the armature, the periphery of the cog was as powerfully magnetised as before.

Even now that I have fitted a solid phosphor bronze cog, there is enough magnetism round the teeth to hold a pin. I am seriously considering fitting another make of magneto, as starting is extremely difficult, and the only plug that I can get to stand up to the work without missing when hill climbing is a Lodge racer.

Handsworth.

N.P.D.

Sir,—In an endeavour to help brother motor cyclists, I should like to place on record my experience of the Dixie magneto fitted to my O.K. Junior motor cycle.

As in the case of your previous correspondents, I had troubles traceable to poor ignition, and finally dismantled the magneto. I found the permanent magnets were in a very poor state, and had them remagnetised, which removed the trouble. Whilst dismounted, it was noticed that the steel of the magnets was so soft as to be very easily marked by drawing a file across them. I am open to correction, but I have always understood that permanent magnets to remain permanent should be of dead hard steel, and it is to this fact, in addition to the steel driving sprocket, that I attribute the loss of magnetism.

It should be noted in reassembling that the magnets must be in intimate contact with the steel bearing plates of the rotor pole pieces, and that they in turn should revolve as close as possible to the sides, as the slightest increase of air gap at these points has considerable effect upon the current.

Another trouble is the rapid pitting of the points, the cause of which I have not yet been able to ascertain.

F.C.C., Capt. R.A.

BENZOLE.

Sir,—A question of vital importance to motorists of all classes is at present being decided by a new association, known as the National Benzole Association. I believe this body is mainly composed of manufacturers of benzole products. I have reason to believe that a circular letter has been sent to all producers of benzole, giving a suggested specification for motor benzole. As one who for some considerable time has been manufacturing motor spirit, I can truthfully say that benzole fulfilling this suggested specification will not appeal to motorists after a few trial runs; and the only persons who are going to benefit to any extent are the producers of the spirit. On the face of the letter, I do not think that any motor engineer or chemist has been consulted. Furthermore, the price of the spirit is 3s. per gallon, which, again, is detrimental to the country, considering the tremendous amount of benzole which is now being produced.

I suggest, then, that the Benzole Association should call to a meeting the chemists who manufacture the product and one or two good motor engineers and hear their views on the subject, and I am quite certain that the result will be a product which will—if not quite equal to petrol—at least give satisfaction and be worthy of the good name benzole producers received during the war.

MOTORIST AND CHEMIST.

[This letter was submitted to the National Benzole Association, who state that the quality of the benzole has been decided by experts, and is, of course, subject to revision from time to time.—ED.]

An electric bicycle used with a delivery sidecar by the Willard Storage Battery Service in Pendleton, Ore., U.S.A. An old motor cycle, sans engine, and a "starter" from an automobile, with a storage battery, form this interesting combination.

TANGENTS OF OBSERVATION.

Sir,—There have been several letters on this subject, but I have not noticed that the correct answer has been published.

Excluding refraction, the distance (D) which can be seen in miles from a height (H) feet is $\frac{2R}{5,280} h = D^2$.

(2R is the diameter of the sphere and 5,280 is the number of feet in a mile.) This is geometrically true when h is small compared with 2R. As the diameter of the earth is roughly 8,000 miles, this formula reduces to $h = \frac{2}{3} D^2$ almost exactly.

The effect of refraction near the surface of the earth is generally taken as $\frac{2}{21} D^2$, so that the formula becomes

$h = \frac{4}{7} D^2$, or $D = 1.32 \sqrt{h}$, or about 8% less than the figure given by Gunner Harle on January 16th.

In the winter of 1893 with the naked eye I saw Mount Etna in Sicily (height, 10,865 feet) from Valetta in Malta—a distance of 125 miles.

The weather is seldom clear enough to see this distance, but the sight is certainly possible. The refraction of astronomical objects at the horizon is about half a degree, but then the whole atmosphere is looked through. The method of combining the heights given by Gunner Harle is correct. The heights must not be added, but two sums must be done. London. J.H.H. (MAJ.).

THE THREE-JET BINKS CARBURETTER.

Sir,—Referring to Capt. Lindsay's further letter as to the supposed dead spot in my carburetters, I would like to state again, and most emphatically, that if there is no fault in the construction of the carburetter this dead spot does not occur.

I only wish that I could get my esteemed client, Capt. Lindsay, over to our works with a machine in which he says he experiences a dead spot, and I would stake my reputation that I could put this right in a few minutes. I would also like to point out that, although Capt. Lindsay has done me the honour of using my carburetters on no fewer than thirty-seven machines, he has never even drawn my attention to it in a letter. The matter must be only trivial, otherwise so experienced a motor cyclist would never have used my carburetters so consistently; but to arrive at something final on this matter, I would suggest that it be definitely ascertained and stated by an independent party, such as yourself, whether a dead spot is there or not. I suggest that I attend at your editorial offices with a machine fitted with my ordinary three-jet carburetter, and that it be then and there tested by you, or someone you may appoint. If the dead spot is there—well it is there, and there is an end of it; but if it is not, it must prove what I say—that no dead spot is or should be there. The result of this test to be considered final, and published in your paper. C. BINKS.

[We shall be pleased to undertake the suggested test and to report upon it, but we would point out that the only thing it will prove will be the absence of a dead spot in the particular carburetter with which the test is made.—Ed.]

WAR-TIME MOUNTS.

Sir,—Since July, 1914, I have owned the following: Quadrant, Triumph, Warne cycle car, 1914 6 h.p. Royal Enfield, Douglas, 1915 6 h.p. Enfield, and, again, a 2½ h.p. Douglas (my present mount).

I have been a rider continuously since 1903, and on looking back over four years of war one wonders how we have kept on the road at all. My official duties have given me many rough journeys, and, like many others, I have had to do most of my own repairs. Coming home to Brighton on a very dark and rainy night, with both bottom fork links broken, carbon brush broken, and a belt link lin. instead of ¾ in., is no joke on a Douglas, I can assure you, although I had a stout strap to hold the front forks to the rest of the machine. On the pot-holey roads from Lewes to Brighton I did not average twenty miles per hour, and, furthermore, I did not try.

My Quadrant, which had a hub gear, I sold, and subsequently obtained a Warne cycle car, as I wanted protection from the elements. May I be forgiven for deserting a motor

cycle. I have distinct recollections of overheating, breaking valves, and tremendous petrol consumption whenever I tried to keep the 'bus covering thirty miles in the hour. This was a useless proposition to me, because the whole thing wanted thoroughly overhauling, and in war-time no one could be found to do the job.

To carry on, I bought a single-speed 1910 Triumph, and as I prided myself on always having an up-to-date "iron," this was nearly the limit. We went together for many, many miles all over Sussex, but did I not have to pedal up some of the hills? I called on some friends one day, and left it against a tree. When I came out of the farm I could not get it to fire, although I tried for one and a half hours. I was stranded seven miles from the nearest station, so the Triumph was left there until the Sunday, when we were both ignominiously towed home by another Triumph. The joke of the whole thing is that immediately I got home, and, without doing anything except putting on the belt again, the old 'bus fired, and was never any further trouble.

Many little things, such as using small wire nails for chain rivets, Chinese lanterns when carbide gave out and none could be bought, getting paraffin from country cottages before the engine cooled, going without a decent meal for seven and eight hours at a stretch because country places gave up making meals owing to the rationing scheme, were all in the day's run, and helped one to realise what the "boys" over there are going through.

For some time I had the loan of a 1915 3½ h.p. Sunbeam combination, and never was a sweeter 3½ h.p. made. My wife and I went from Brighton to Manchester, and took five days to get back: held up in Birmingham for two days, dug out of 15ft. snowdrifts in the Vale of Evesham, wet through (and, owing to snow penetrating the 'bag, no change of clothes) at Oxford, but nothing except kindness shown everywhere. Never a misfire from the engine all the way; and when I say I had to take off the footboards and front mudguard, frictioned a back tyre through, and knocked off the silencer, it will be noticed it was "some" ride. In 1916 I did the run from Brighton to Manchester in one day on a 6 h.p. Enfield which had been hammered for over two years, and except for a puncture I had no trouble whatever, and got to a theatre in the evening.

My many changes of machines have been necessary because big repairs could not be done under a long period, although I could get a Class A priority certificate. I could only sell out and buy another machine. I found that to pay a good price for a reliable second-hand machine was the only way out, and I think this is a method that will pay others in the near future. I practise what I preach when I state that a fortnight ago I gave £45 for my present 1914 2½ h.p. Douglas, but its condition is practically perfect.

I have fifteen years' experience of motor cycling, but, like many others, I will give it up and take to a bath chair with auto-wheel attached before I will give £150 for a motor cycle and sidecar which to-day, as in 1905, covers me with mud and road filth, and requires six hours' solid work to clean it after 150 miles round Sussex on a bad day. We are a cheery lot, but there are limits even to our expenditure for our pet hobby. WM. WILSON.

SUMMARY OF CORRESPONDENCE.

A reader, Mr. R. W. Lewis, Beverston, St. James's Square, Cheltenham, would be glad to hear from any other reader who is suffering from a similar misfortune to himself, namely, the amputation of the right arm at the shoulder, who could tell him how best to control a sidecar combination, and also which type would be most suitable for his needs.

THE BAILY CRANKLESS ENGINE.

A Revolutionary Idea in Power Transmission.

THIS unusual engine, which is the subject of the accompanying illustration, has been submitted to us as having been run successfully in Australia four years ago.

As will be seen, the main feature of the design is the elimination of the crankshaft, the cylinder being in axial alignment with the main shaft.

This method of construction is not new, however, as the utilisation of a helix to convert the reciprocating motion of the piston to a continuous revolving one was embodied in the "heli-crank" steam engine designed by Mr. C. Hyde Beadle in 1898, and later by Messrs. Moonbeams, Ltd., who applied the principle to a petrol engine. Unfortunately, nothing came of this latter, and the design was eventually dropped.

The Working Principle.

The Baily engine is of the double-acting four-stroke type, explosions taking place at both sides of the piston. The method of working will be obvious from the drawing. Each stroke of the piston rotates the main shaft one complete turn by the pressure of the "teeth" in the crosshead on the diamond-shaped portions of the helices. The flywheel is attached to the end of the shaft. The smaller shaft, which has a slower thread helix, serves to

The Baily crankless engine, showing how the reciprocating motion is transformed to a rotary one by means of a helically threaded shaft.

start the crosshead on the return motion at the end of each stroke. It is driven by gearing from the main shaft as shown. Both the shafts are on tapered roller bearings, which are adjustable from the outside.

On turning to the piston and cylinder construction, as shown in the drawing, several grave defects become apparent. Whether these have received attention in the actual engine or not we cannot say. It does not need any great effort of the imagination to picture the piston rod and head, after a short period of running, in a state approaching the incandescent,

and the introduction of lubricant presents no small difficulty. According to the drawing, the bore and stroke are 86×102 mm., giving a total capacity of 1,120 c.c. after allowing for the piston rod in the one side. As the clearance shown amounts to only half an inch, the compression ratio is grossly exaggerated.

Points to be Overcome.

On going into details, further discrepancies disclose themselves, such as the rotating speeds. The guide rod is geared 8 to 1 from the main shaft, so that at the quoted speed of 3,000 r.p.m. (6,000 strokes), at which the engine is said to run smoothly, the guide rod is turning at the rate of not less than 48,000 r.p.m.! The valves are operated through cranked levers bearing on a camshaft, which runs the whole length of the engine, parallel to the mainshaft.

The overall dimensions are given as 10×22 in., and the engine is said to develop 16 h.p. at 1,000 r.p.m. A new engine has also been designed, weighing 40 lb., to develop 44 h.p. at 2,500 r.p.m.

Doubtless all the faults indicated are capable of being overcome, and we think the design deserving of more than passing notice, in view of the possibilities it seems to possess in the way of balance and compact construction.

The original helicrank steam engine on which the principle was first successfully adopted.

AMERICAN VIEWS OF BRITISH MACHINES.

WE are particularly interested in the views of American despatch riders, many of whom have been riding British-made motor cycles at the Front. The poet Burns aptly emphasises the importance of seeing "ourselves as others see us," but it has been part of our insular nature to consider that English motor cycles are pre-eminently supreme, and that nothing can be learnt from foreign manufacturers. That English motor cycles are supreme we know, but this does not mean that we cannot learn a good deal from the makers of other countries.

One correspondent writes to *Motor Cycling and Bicycling* of Chicago: "Talking about riding motor cycles, I might say that I am mounted on a British one-lunger, belt drive, and three speeds. I imagine it is good for forty-five all out, but who wants to ride—or

rather can ride—that fast on these delightful roads? It is a low-hung machine with 26 in. wheels, easy to handle, somewhat like a Cleveland—that is, the fork is the same, but it is driven with a V belt instead of chain. I never had a bit of trouble with it, and I have been putting the tiny thing through its paces for the past twelve months, so I can say this much for it: it is good, though small—the right kind of mount for this kind of work."

Another correspondent to the same journal declares his views on English machines in no uncertain terms. Needless to say, these are the opinions of the rider and not of this journal:

"During my time as a D.R. I have had six Douglas machines, an English make, two-speed, twin-cylinder, opposite motor, weighing about 125-150 lb., $2\frac{3}{4}$ h.p., no clutch, and belt drive. The

motor is very smooth running, but the carburettor, like the majority fitted on English machines, is a joke. I rode a —, the best single-cylinder machine I have ever seen. This was a three-speed mediumweight model, just right for the conditions over here. It is a machine of few parts, with belt drive. There are other makes of machines 'over here' in the war game, but I prefer the — to any as a solo machine. The sidecar outfits are numerous, and I have driven, of the English make, Clyno, Rudge, and Douglas. There are many objections to English machines, such as weak and awkward frames, low-powered motors, queer handle-bars, clumsy controls, no equipment, not a graceful or symmetrically built machine. Of course, they have good points. My objection to American-made machines for solo use over here is too high a saddle position.

QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Overhauling a Zenith.

[?] I have been overhauling my machine, a Zenith-Gradua, and cannot get the back wheel out of the frame, nor the sliding plungers which carry it. Please let me know the best way to get it out.—T.T.

If the wheel is on a machine dating from 1912, the plungers carry the fork ends, and the wheel may be removed by loosening the two axle nuts; but if of 1911 date or earlier, the plungers themselves must be removed, as they are screwed on to the axles. Everything in the way of the wheel should be removed, such as mudguards, etc., and the two caps at the rear ends of the fork taken off, and then the gear should be completely unscrewed. This is rather a troublesome job, but it can be done by an amateur.

About the F.N.

[?] (1.) Could you tell me the year of a 4.5 h.p. four-cylinder F.N., frame No. 35,757 (no number on engine)? (2.) It has no clutch. Could you give me details of F.N. clutch, and, if one can be fitted, should I be able to obtain one? (3.) It has no speed gear. Could one be fitted, or could the bevel gear be screwed to a two or three-speed hub? (4.) Can I obtain jets for a *breveté* single lever carburetter, and how does one adjust it to run slowly? It will hardly fire below 10 m.p.h. (5.) Is there any special setting of the valves? The exhaust is set to close as the piston reaches the top of the stroke. What lift should the a.o.i.v. have? (6.) And, lastly, what is the maker's name, and what do the letters F.N. mean?—F.H.

(1.) You will have to send this information to the agents, F.N. (England), Ltd., Efenmo Works, Kimberley Road, Willesden, London, N.W.10. (2.) The clutch is of the multi-disc type, and full information can be obtained from the firm. (3.) The firm could also possibly fit you up with a two-speed gear. A hub gear could not be fitted. (4.) The word *breveté* merely means patented. We presume the carburetter in question is an F.N. Successful adjustment of the automatic inlet valves and carburetter is the secret of slow running. (5.) Your idea of setting the exhaust valve is correct, but the inlet valves should have an opening of about $\frac{3}{32}$ in. (6.) The machine was manufactured by the Fabrique Nationale d'Armes de Guerre (the Belgian Small Arms Co.), of Liège.

Wiring.

[?] I have just purchased a 1914 Harley-Davidson. The previous owner has had it stored for several months, and when removing the accumulator he did away with all the connections, and I cannot see how to connect it up to the dynamo. Please give me the useful information.—F.H.B.

The negative terminal of the accumulator goes to earth, the earth terminal being a screw on the outside of the battery box; the positive terminal to the generator. If a vacuum switch is fitted, connect this to the top terminal on the switchbox; but a manual switch should be attached to the bottom terminal on the bottom fuse.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication.

ILIFFE & SONS LTD.

Dismantling a Gear Box.

[?] I shall be obliged if you will tell me how to dismantle the gear box of a 7.9 h.p. 1916 model American Excelsior. I have removed the box from the frame, opened the clutch and removed the plates, also one circular nut on the shaft, but I cannot get the inner portion of the clutch, including the chain wheel, off the shaft, and it is apparently necessary to remove this to get at two of the screws which hold the gear box shell together. I have tried gentle hammering of the shaft supporting the chain wheel, but without result. I do not want to use too much force. The other end of the shaft, the one carrying the small chain wheel and the kick-starter ratchet, does not seem to be any easier to dismantle. If you can give me any directions for dismantling the gear box I shall be extremely obliged. There are some indications of feathers, but I am not sure, and if they exist there seems to be no way of extracting them. Are there any left-hand threads?—J.W.O'N.

To remove the chain wheels, get two hard wood wedges and drive them one each side of the chain wheel, between it and the gear box; then screw the nut on a couple of threads and hit it smartly with a hammer. This should drive the wheel off without difficulty, or you may hit the end of the shaft with a heavy mallet or a lead hammer; it does not matter which so long as you take precaution that you do not damage the thread. The shafts are tapered and the chain wheels are secured by keys.

Racing.

[?] (1.) What is the distance of a Brooklands lap? (2.) A friend of mine had a 1912 Zenith, and in wet weather he found the gear lever almost impossible to turn. Is this always so on Zeniths? (3.) What is the address of the owner of Herne Hill racing track, and also the address of the owner of Canning Town track?—J.S.N.

(1.) The distance of one lap at Brooklands Track is 2 miles 1,263 yards. (2.) No; the trouble was probably due to grit, and could be cured by washing out with paraffin and oiling. (3.) Herne Hill is owned by the London County Athletic Club, Burbage Road, Herne Hill, London, S.E., but Canning Town track no longer exists.

EXPERIENCES WANTED.

"A.W.F." (Knutsford).—Four-cylinder 8-10 h.p. Henderson and sidecar. Consumption, speed, reliability, and hill-climbing capabilities; brake power.

RECOMMENDED ROUTES.

RUABON TO BLACKPOOL.—R.G.T.
Ruabon, Wrexham, Chester, Birkenhead, Liverpool, Ormskirk, Rufford, Tarleton, Longton, Preston, Kirkham, Blackpool. Approximate distance, 76 miles.

COVENTRY TO MANCHESTER.—A.B.
Coventry, Fillongley, Kingsbury, Fazeley, Lichfield, Armitage, Rugeley, Great Haywood, Stone, Newcastle-under-Lyme, Congleton, Wilmslow, Cheadle, Manchester.

NORTHAMPTON TO RIPLEY (DERBYSHIRE).—N.G.B.

Northampton, Kingsthorpe, Brampton, Husbands Bosworth, Wigston, Leicester, Mount Sorrel, Loughborough, Derby, Little Eaton, Ripley. Approximate distance, 56 miles.

"The World's
Best
Motor Cycle."

The A.B.C. Motor Cycle is
the result of

**SPECIALISED
KNOWLEDGE**

and establishes a new era in
design and construction.

Godfrey's, Ltd., have pleasure in announcing that they have been appointed Sole Distributing Agents for London and District, taking in the whole or part of the following counties: Middlesex, Essex, Hertford, Buckingham, Surrey, and Kent.

They will be pleased to hear from Agents desirous of representing the A.B.C. Motor Cycle in their district.

Detailed particulars and prices will very shortly be issued.

It is an A.B.C. proposition and an All chance not to be missed, so get in touch with Godfrey's right away.

GODFREY'S, LTD.
208, Great Portland Street, London, W.1.

'Phone : 7091 MAYFAIR (2 lines).

In answering this advertisement it is desirable to mention "The Motor Cycle."

TWO GOOD THINGS!

N.U.T.s

3½ Twin, Three-speed.

METRO-

TYLERS

2½ Two-stroke, Single and Two-speed.

We beg to announce that we have been appointed sole agents for the sale of the above two well-known motor cycles for the following districts:

The whole of LONDON and of the counties of MIDDLESEX, KENT, SURREY, SUSSEX, ESSEX, HERTFORDSHIRE, and a portion of BUCKINGHAMSHIRE.

We have acquired the sole selling rights for the machines mentioned over the above districts, and are now able to book orders for definite delivery. We are also open to consider the appointment of suitable sub-agents, and anyone interested should get into early communication with us. The principal details of the machines are as follows:

A. The N.U.T., made by the Newcastle-upon-Tyne Motor Co. This machine was famous before the War, both for speed and reliability. The firm are concentrating all their energies on the production of one type—a super-efficient 3½ h.p. “V” Twin, three-speed countershaft gear, hand clutch and kick start. This machine has done wonderful things on test, details of which will shortly be available. It is equally suitable for solo or sidecar work, for speed on the open road, or flexibility in traffic. The price is not yet definitely fixed, but will be announced at an early date. Definite delivery can be given in MAY, and the price will be competitive.

B. The METRO-TYLER. This machine is the outcome of the combination of two firms, both well known before the War as the respective makers of the METRO and TYLER Lightweight Motor Cycles. The best features of these two machines have been combined, with the result that a super-excellent lightweight has been evolved.

This is a 2½ h.p. two-stroke, of most attractive appearance, the frame having a sloping top tube, with sloping tapered tank. The machine is fitted with Brampton Biflex Forks, and is luxuriously equipped throughout. It is finished in dark red, and disc wheels can be added if desired. The engine is super-efficient, giving good speed, flexibility, and perfect firing at all speeds and under all conditions. A demonstration model can be inspected at our Hampstead address.

PRICES: Two-speed Model, **£52 0 0**

Single-speed Model, **£46 0 0**

EXTRAS: Disc Wheels . . . **£2 10 0** the set.

Long Plated Exhaust Pipe, **10s.**

DELIVERY—Fourteen Days certain.

We shall shortly be opening extensive showrooms in Great Portland Street for the exclusive handling of these two machines, and we confidently recommend them as the very best of their respective types. Meanwhile, we invite prospective purchasers, both private and trade, to get into immediate touch with us. A supply of catalogues for both the above will shortly be available.

Remember also that our stock of other new and second-hand machines is still the best in London, and that we can book your order for earliest delivery of **ANY** make.

Phone: Hampstead { 5392

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd., and crossed** & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4.), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

RIDER TROWARD and Co., 31, High St., Hampstead.—Orders now being booked for earliest delivery 2-speed and clutch Allons, £58; also De Luxe models, with kick start, £65. [2258]

ALLON, 1919, single-speed, £39/12; also 1916 2-speed, hand clutch, all accessories, £42/10, also 1915 2-speed, all accessories, £36; exchanges arranged.—Lamb's, 151, High St., Walthamstow, and 50, High Rd., Wood Green, N. [3206]

Antoine.

3h.p. Antoine, requires slight repairs; £11, offers.—B., 76, Grange Walk, Bermondsey. [2961]

Ariel.

1914 3 1/2 h.p. Ariel, new condition; £25, bargain.—29, St. Leonard's St., Bromley-by-Bow. [3094]

ARIEL, 1915, 6h.p., electric lights, 2-seater sidecar; £77/10; exchange Mags or 2-seater.—255, Darlish Rd., Bournbrook, Birmingham. [X2876]

5-6h.p. 1914 Ariel, T.T. bars, many extras, Millford Empress sidecar; £46; exchange for first-class Morgan with adjustment.—Lt. Ellis, Gratsa. [X2691]

RIDER TROWARD and Co., 31, High St., Hampstead.—New 3 1/2 h.p. 3-speed Ariel in stock, £80. Orders being booked for earliest delivery 5-6h.p. combination. [2257]

Auto-Wheels.

WALL Auto-Wheel, with cycle, in sound running order, and complete; £12, no offers.—Lt. Frain, R.A.S.C., Grove Park, S.E. [X2862]

Bat.

8h.p. Bat, late 1913, hardly used during war, 2-speed, kick starter, spring frame, 3 lamps, 3 generators, unspratched, canoelet sidecar; £62, or exchange for slightly lower power combination.—7, Park Hill Rise, Croydon. [2950]

Blackburne.

RIDER TROWARD and Co., 31, High St., Hampstead.—Orders now being booked for earliest delivery of new Blackburnes; 2 1/2 h.p., 2-speed, clutch, £60; 4h.p., 3-speed, £80; 6h.p. combination, £125, or with spare wheel £130. [2256]

Bradbury

4h.p. Bradbury, 3-speed, and sidecar; quick sale £30.—Clapham (Motors), 119, King George St., Greenwich, S.E. [X2927a]

1912 4h.p. Bradbury, 3-speed, good condition; £26, or near offer.—Taylor, 16, Guys Cliffs Terrace, Warwick. [X2836]

BRADBURY, 1912, 3 1/2 h.p., little used, engine as new, condition generally perfect, with Lucas head lamp and accessories; £18.—Hall, next to Green Man, High Rd., Whetstone, N.20. [2949]

Brough.

BROUGH, 1916, 3 1/2 h.p., S.A. countershaft, h.b. controlled clutch, semi-T.T. Amac, Thomson-Bennett mag.; £55.—Lawrey, 26, Clarence Rd., Walmer, Kent. [3048]

MOTOR CYCLES FOR SALE.

B.S.A.

B.S.A., 3-speed, 1919 models in stock.—Reys, 378, Euston Rd. [2972]

NEW B.S.A.'s in stock: immediate delivery Model K.—Alexander, Agent, Wallasey Village. [1506]

1919 New B.S.A., 4½ h.p., belt-cum-chain; £79/16; exchanges considered.—Deane, Matlock Bath, Derbyshire. [X2906]

B.S.A., 3½ h.p., 2-speed, F.E., good condition, engine overhauled; full particulars on application; £220.—Morgan, 6, Ash Ville, Tredegar, Mon. [2971]

DELIVERY from Stock of Model K B.S.A. chain-cum-belt 4½ h.p.; £79/16.—Elce and Co., 15-16, Bishopsgate Av., Camomile St., E.C.3. [0552]

1917 Model K B.S.A. and Coachbuilt Sidecar, fully equipped, under 1,000 miles; also 1916 model, as above; sell either one.—Coffin, Holwell, Sherborne. [X2958]

B.S.A. (2), belt-cum-chain models; 76 gns.; actually in stock; exchanges arranged.—Lamb, 151, High St., Walhamstead, and 50, High Rd., Wood Green, N. [3201]

1917 B.S.A. Combination, all chain drive, 2-speed, kick start, speedometer, apron, lamps, perfect condition; £90, or exchange higher power.—Melrose, 1, Kenton Rd., Tooting. [3031]

1913 B.S.A. Combination, 2-speed, free engine, kick starter, complete with lamps, horn, and generator, in excellent condition; £38/10.—Emsen, 58, High St., Finchley, N.12. [3137]

B.S.A.—For the earliest possible delivery of 1919 models, advance specifications and prices, sole district agents, The Walsall Garage, Wolverhampton St., Walsall. 'Phone: 444. [X0126]

1917 4½ h.p. Chain-cum-belt B.S.A., in excellent condition, new cover and tube to rear wheel, original tyre on front, lamps, horn, and accessories; owner bought car; £60.—Drake, Sutton, Ely. [X2787]

FOR Earliest Delivery B.S.A., place your order with us. Free insurance policy with every machine ordered before March 7th.—The Brook Motor and Engineering Co., Withington, Lanes. [X2727]

RIDER TROWARD and Co., 31, High St., Hampstead.—New 4½ h.p. B.S.A., chain-cum-belt, in stock, £279/16. Orders being booked for earliest delivery chain drive model, £31/18. [X2592]

B.S.A. 1916-1917 4½ h.p. Cycles, with 3-speed gear box and countershaft, with sidecar, complete with lamps; prices £75, and £80 respectively.—Apply to Lebus's Garage, Ferry Lane, Tottenham, N. [2932]

WALBRO Motor Works, Ely, Cambs.—B.S.A. 1914 combination, No. 1, £29 sidecar, 3-speed countershaft, chain-cum-belt; this combination is absolutely as new, only ridden about 6 months, plating and enamel good as turned out from works; £65. [X2592]

4 h.p. B.S.A., late 1914, and excellent Gloria sidecar, all-chain drive, 3-speed, stored 2 years till lately, exceptionally powerful engine, mechanic owner; full particulars on request; £55, lowest; this is a genuine bargain.—Box L8,811, c/o The Motor Cycle. [2929]

Calthorpe.

1919 Calthorpe 2-stroke, absolutely new, 2-speed, free engine; 39 gns.—Stevens, Louvaincourt, Ashstead. [X2952]

CALTHORPE Motor Cycles.—All models in stock for immediate delivery: no permits required.—P. J. Evans, 91, John Bright St., Birmingham. [0955]

RIDER TROWARD and Co., 31, High St., Hampstead.—Calthorpes, 2½ h.p., 2-stroke, 2-speed, 40 gns.; 2½ h.p., J.A.P., 2-speed, 45 gns.; immediate delivery. [X2260]

CALTHORPE Junior, lightweight, 4-stroke, 2 speeds, free engine, Dunlops, perfect order; price £20; seen by appointment.—R.B., 136, Harrington Rd., South Norwood, London, S.E. [2937]

1916 2½ h.p. Calthorpe-Jap, Enfield 2-speed, drip feed, sloping tank, lamps, tyres excellent, machine perfect order; £34, or would exchange Morgan.—Bennett, Ridgeway, Cumnor Hill, Oxford. [2943]

CALTHORPE-J.A.P., 1915, 2½ h.p., Enfield 2-speed, Lucas lamps, Senspar, X'Fall saddle, useful accessories, spares, excellent condition; seen week-ends or appointment.—13, St. George's St., Ealing. [3060]

1915 2½ h.p. Calthorpe-Jap, 2-speed Enfield gear and clutch, Stewart speedometer, Lucas head and tail lamps, mechanical horn, mileage 2,000, excellent condition; 27 gns.—Hayercraft and Son, 31, Tranquil Vale, Blackheath. [X2826]

CALTHORPE Lightweight (4-stroke), 2-speed, first-class condition, engine, enamel, and plating; £24; exchange 3½ h.p. cash adjustment; Jones speedometer, 80 m.p.h., new, unused, £3/17; Pasha head light (self-contained generator), 12/-.—Richardson, 72, Edgbaston Rd., Birmingham (D). [2940]

Camplon.

1918 Camplon-Jap, 2½ h.p., 2-speed, free engine, lamps, generator.—Simpson, 274, Well Hall Rd., Eltham, London. [2960]

4 h.p. Camplon-Jap, N.S.U. 2-speed, in good order; £20, or offer.—Gutteridge, Watchmaker, Market Harborough. [X2866]

WALBRO Motor Works, Ely, Cambs.—Camplon 1914 2-stroke; all in nice order, 2 new Dunlop studded tyres, Bosch mag., good belt, mechanically sound; £24. [X2593]

Sole London Agents

for

and

British Excelsiors.

WITH BRITISH BRAINS AND

BRITISH MATERIALS—BEHIND

THEM.

Designed to meet the requirements of both novice and expert. A tour can confidently be taken anywhere—at any time—inexpensive to run, but as reliable as the most expensive car. No outlay from tyre troubles when carrying the A.I.S. spare wheel, included in the price charged for the whole outfit. A boon to the keen commercial man and doctors. If you desire to tour peacefully at Easter, please communicate with us immediately. We have large contracts for the following makes:

A.J.S., EXCELSIOR, TRIUMPHS, DOUGLAS, ENFIELDS, B.S.A., P. & M., HENDERSONS, HARLEY-DAVIDSONS, IMPERIAL J.A.P.'S, Etc.

May we send you particulars?

Special consignment, just arrived, of Sidecar Chassis, dual frame, 650x65 wheel for underslung hodies, suitable for 6-8 h.p. machines. Price (less tyre) .. £7 19s. 0d. Price for 3½ h.p. machines .. £6 17s. 6d.

Watsonian Coachbuilt Sidecars, for 2½ and 3½ h.p. machines .. £15 10

Handlebars, Douglas T.T. pattern, ½ in. or 1 in. stem .. price 15/-

F.W.R. Aluminium Electric Head Lamps, for lightweight .. price 12/6

Ditto, Sidecar Lamps .. " 9/11

Ditto, Tail Lamps .. " 9/11

Sidecar Lamp Brackets .. " 1/6

4½ volt. H.H. Batteries .. price 13/6

4 volt 20 amp. Store Accumulators —

4 volt 40 amp. Store Accumulators —

4v. 2cp. bulbs for same .. each 9d.

Triumph Mechanical Horn, for top tube or handlebar 27/6

Repair rents in your overalls or mackintosh with Mend-A-Tear, supplied in khaki or black price 1/- (Postage, 3d.)

Lucas and P. & H. Lamps and Horns in Stock. A limited supply only.

H. TAYLOR & CO., LTD.

Showrooms: 21a, TORE STREET, W.C.1. Wholesale: 38, ALFRED PLACE, W.C.1.

Garsie: Tottenham Court Road. 'Phone—Museum, 1240. Telegrams—"Dynametro, Westcent, London."

MOTOR CYCLES FOR SALE.

Camplon.

CAMPION-J.A.P., 4h.p. twin, 2-speed countershaft and clutch, all-chain drive, 1914 model, running order, but needs overhauling; £30.—Longman Bros., 2, King's Parade, Acton. Tel.: 1578 Chiswick. [3172]

Chater-Lea.

1915 Chater-Lea, No. 7, 8h.p., 1916 engine and gear box, light C.B. sidecar, Indian red disc wheels, perfect; £75.—Gerard, 10, Belmont Av., Edmonton. [3014]

CHATER-LEA, 8h.p., Jardine 2-speed countershaft, all-chain drive, nearly new tyres all round, extra large sidecar, generator, 3 lamps, just been enameled throughout, little used during war; exchange for less power Douglas, or B.S.A. preferred, or sell £48; after 6, or a P.C. before.—A.G., 5, Mansell Rd., Acton, W.3. [2918]

Chater-Lea-Jap.

1911 Chater-Lea Combination, No. 7, 8h.p. J.A.P. engine, 1918 pistons and cylinders just fitted Binks carburettor, 2 tanks fitted, will run on paraffin; £45.—Jackson Bros., Builders, Eastleigh, Hants. [X2758]

Clyno.

CLYNO.—Earliest deliveries. Your name on our list ensures this.—Martin Mitchell, Ltd., Stafford. [X2920]

CROW Bros., High St., Guildford, West Surrey agents for the 1919 Clyno. Order now to ensure early delivery. [1563]

6h.p. Clyno Coachbuilt Combination, 2 speeds, chain drive; £36.—27, Wilton Av., Chiswick, London. (After 7 o'clock.) [3182]

1914 5-6h.p. Clyno and Sidecar, 3-speed, condition as new, very little used, new Stewart speedometer; price 55 gns.—Dapp, Altona, Radlett, Herts. [2986]

CLYNO Combination, 5-6h.p., large luggage carrier, etc.; £40; also Ilex solo, requires ignition and few new spokes; £15.—Hills Garage, Dartmouth. [X2722]

CLYNO 6h.p. Coachbuilt Combination, 2-speed, kick start, lamps, horn, speedometer, etc.; best offer over £40 accepted.—Apply, Motor, 80, Bromfield Rd., Clapham. [X2759]

CLYNO Combination, 1916, 6h.p., 3-speed, kick start, spare wheel, luggage carrier, petrol can holder, electric lamps, tools, spares, splendid condition; any trial; must sell; £85.—Ivydell, Southfield Park, Pinner, Middlesex. [X2891]

Connaught.

1915 Connaught, 2-stroke, new Dunlops; 17 gns.—Chalkley, 2, The Broadway, New Southgate. [3132]

Coventry Eagle.

COVENTRY Eagle, 1915, 2-stroke, T.T., perfect little machine, as new; £24.—51, Maplethorpe Rd., Thornton Heath. [3030]

Diamond.

DIAMOND, new 2-stroke, with 2-speed gear; 37 gns.; exchanges.—Parker's, Bradshawgate, Bolton. [X2901]

DIAMOND, new Xmas, 1917, 2½ h.p. J.A.P., 2-speed gear, clutch, P. and H. lamps, horn, new tyres, excellent condition; £34.—P. Granger, Wyke, Hudd. [X2775]

Dot.

8h.p. Dot-Jap, 1912-1913, 3-speed Chater gear, kick start, handsome coachbuilt sidecar, little used, lately overhauled, lamps, fast, powerful, rare bargain; £59; also 7h.p. Bat-Jap, Whittle, sidecar, 2-speed Fittall gear to fit, sporting combination, £21, near offers considered.—Gordon, c/o Jones, 17, Cleveland Mews, London, W. [2991]

Douglas.

NEW Douglas in stock shortly at Gourlays, Fallowfield, Manchester. [1781]

DOUGLAS, 1914, 2-speed; £40; any trial.—J. King, 123, Pownall Rd., Dalston. [3063]

1914 Douglas, 2 speeds, sound, but wants tuning up; £22.—Cross, Jeweller, Rotherham. [X2916]

DOUGLAS, 1915, 3-speed, 2½ h.p., in good condition; £42.—Box 2,744, c/o The Motor Cycle. [X2724]

DOUGLAS, 1915, 2½ h.p., 3-speed, accessories; £43.—Lt. Disney, Rossie, Kingston Hill, Surrey. [2148]

FOR Immediate Cash, cheap.—Late Douglas, new condition.—Ashby House, Hunstanton, Norfolk. [X2814]

DOUGLAS, 2½ h.p., 2 speeds, T.T. model, very fast; £35.—Driscoll, 58, Woodfield Rd., Ealing, W.5. [3103]

DOUGLAS, 1911-12, 2-speed, running order, lamps, complete; £20, or near.—3, Warren Rd., Reigate. [3120]

2½ h.p. Douglas, 2-speed, new condition; £40; seen any time.—Wright, 113, Blair St., Poplar, London. [3134]

4 h.p. Douglas, 1915 Colonial model, with Phoenix coachbuilt sidecar, accessories; £60.—Ely, Gurs, Maldon. [X2357]

1913 Douglas, 2-speed, just overhauled, good condition; £35.—J.W., 112, Herbert Rd., Plumstead, S.E.18. [X2880]

DOUGLAS in Stock, 4h.p. combination, £95; War Office 2½ h.p. model, £60, new.—Moffat, Yeovil. 'Phone: 50. [1103]

DOUGLAS, 1914, 2-speed, T.T. bars, good condition; 30 gns.—41, Church Crescent, Church End, Finchley, W.3. [3100]

The Clubs a Necessity.

THE old saying "Unity is strength" has many applications, but none more true than that in connection with the attitude we should like to see adopted by motor cyclists toward those who would imperil the national prosperity for which so many of them have given their all. It is a psychological fact that the individual motor cyclist is almost always most apathetic concerning that which affects motor cyclists as a whole, yet when several are banded together to form a club, there is none more ready to stand up for his rights. He forms definite opinions on matters of the moment, and he is not slow to proclaim them. He is all for the common good. In a club the trend of popular feeling can always be gauged. The reserved man finds a mouthpiece in the club secretary, and thus the technical press can translate his wants and pass them on to the legislator and the manufacturer.

The present time is the one fraught with the greatest possibilities and consequences to the motoring community as a whole, and it is only the intensely united action of the individuals and the big associations which represent them that will secure them a hearing in the settlement of affairs which concern them so closely. Here, then, is the opportunity of the clubs. What is to prevent them getting into action at once, picking up the broken threads of 1914? We know only too well how many gallant fellows, the mainstay of their clubs, have laid down their lives in the great cause. Some clubs are almost extinct. Yet the aggregate number of motor cycle enthusiasts is surely greater than in the days before the war. What is wanted is a little recruiting among the newly-fledged devotees of the pastime, more publicity and more enthusiasm among the older club members. There should be no need to await the return of all the afore-time members—there is plenty of material to hand, and there is much to be done in which the clubs can be a vital power if they will. But

they must act at once. The most vital question before the motoring world is at present the fuel question. It is most undesirable that the great petrol companies should obtain the control of the home-produced fuel, benzole, which owing to their organisation and means of distribution is a possibility to be considered and resisted by all motorists.

Rear Lights on Cycles.

AT the present moment there is an ill-advised agitation going on amongst a certain section of the bicycling community for the removal of the regulation compelling all road vehicles to carry rear lights. They believe, or affect to believe, that motorists are the cause of the retention of this regulation. It is quite true that motorists welcomed an Order which was obviously for the public safety and did no more than compel others to do what they themselves were already obliged to do. Everything that can be urged against rear lights on bicycles can also be urged more strongly against rear lights on motor cycles, and yet motor cyclists are not following the German plan of raising a plaintive wail. It is suggested that a bicycle head light enables it to be seen at a sufficient distance; this is true only in the case of about 20% of cyclists. A motor cycle light is generally brighter still, and, moreover, motor cycles are overtaken much less frequently than pedal cycles. It has been suggested in our columns and elsewhere that it is gentlemanly to carry a rear light. We agree: consideration for others is one of the marks of a gentleman—but ridicule has been thrown on this view in some quarters. *Verb. sap.*

Another point: The fact that quite a large number of cyclists carry a red light in front is used to prove that the regulation is complicated. To us it only seems to suggest that the cyclists in question should not be allowed on the roads without a keeper. The only fault we have to find with the red rear light rule is the very inefficient way in which it is enforced by the police.

From a 'Bus Top.

WHEN compelled to travel on a public conveyance in London, eschew tubes and taxis, and mount a 'bus, selecting an off side seat on the top. When seated, do not immerse yourself in *John Bull*, but use your eyes. I had a good pennyworth of smiles by this cheap method the other day—as good as any Chaplin film. It was pitch dark, and the grease was of the greasiest. As we drew abreast of Selfridge's, I heard a terrific squawking from a mechorn, and bending over perceived the ghastliest expression of abject terror I have ever seen on a human countenance. An R.A.F. sidecar was towing a subaltern on a disabled motor bicycle through the thick traffic by a rope about ten yards long. Nearing Marble Arch a vortex of blasphemy steamed up into a shocked sky from the intersecting point of all the traffic lines. There squatted a very frightened officer in a very small car. The bulbs of his side lamps emitted pink pin points of radiance of a c.p. equal to the expiring spasm of a wartime match. The police were deciding what he ought to do: the rest of the traffic was piously declaring where he ought to be. A good penn'orth!

New Motor Cycle Carburetters?

PRESUMABLY, war experience will inspire modifications in road carburetters, especially as road motors are now condemned to use fuel containing about 30% of paraffin. The cost factor may restrict invention where motor cycles are concerned: though there is at least one double choke tube carburetter on the market for our benefit, the accurate manufacture of diffuser jets (e.g., the Claudel-Hobson) is not cheap. I expect the pre-war type of carburetter is tolerably efficient on single cylinders, as it is strongly heated by conduction and fairly well screened from head draughts. But I shall be surprised if we do not see marked alterations in the carburation systems of twins. The combination of a simple mixing chamber, a cool or cold carburetter, and a long, unheated inlet pipe is not good. One designer proposes to lead his inlet pipe clean through the silencer.

Aero Carburetters.

THE other day I had an opportunity of inspecting samples of all the carburetters which were employed on the very latest Allied and enemy aero engines. Carburetters for rotary engines naturally stand in a class apart, and have undergone little development since 1914, but those designed for V, vertical, and radial engines convey one notable lesson. Let it be remembered that the very best petrol has been reserved for aviation—stuff which evaporates if you spill it, instead of leaving a wet stain for two or three days, as our own viscous No. 3 does. In spite of this designers have evidently found that aviation spirit takes a lot of atomising, and their notions imply that

all pre-war carburetters, whether of the car or cycle type, failed in two respects. (1.) They did not atomise the petrol properly. (2.) They did not mix the petrol and air efficiently. I deduce this from three points in the design of 1918 aero carburetters. First, the prevalence of hot water jackets for the mixing chambers. Secondly, the measures taken to heat the main air supply, e.g., by inhaling all air through the crank case. Thirdly, the almost universal application of the double choke tube principle, which (a) partly corrects the tendency to over-rich mixture at high speeds, and (b) creates a specially strong suction centre around the jet, thus breaking up the petrol and mixing it more thoroughly with air.

New Magnetos.

FEW of us have any quarrel with pre-war magnetos, except in so far as the contact breaker arm used to stick up, and this was seldom an affliction to any but the very greenest novice, as the rest of us had suffered from it so repeatedly. Study of the patent lists will show that umpteen inventors have damp-proof contact breakers on the brain, and they will doubtless be standardised in due course. The next commonest trouble related to the pick-up brushes on the high-tension slip ring. These occasionally broke, and occasionally short-circuited owing to "tracking," i.e., an accumulation of carbon dust and oil on the brush path. The war has produced a number of "jump spark" distributors, in which the tip of a metal brush passes a contact segment at a small clearance, so that neither fracture nor shorting can occur. We shall not object to this if it comes our way. With the development of very light engines, the weight of magnetos begins to look excessive. The use of aluminium alloys has cut down the weight of six-cylinder magnetos by nearly 50% during the war, but since the armature and magnets account for the bulk of a tiny single or twin-cylinder magneto, we can hardly expect any marked reduction in our class. Moreover, the price of aluminium is still prohibitive.

A Possible Ignition.

AS many know, the famous Liberty aero engine has no magnetos, but is equipped with coil and accumulator ignition of a very interesting type, which is practically as reliable in use as a magneto. Its special features consist of duplicate main contact breakers and a generator which perpetually renews the youth of the accumulator. As the contact breakers are in duplicate, troubles and adjustments are infrequent. No sane motor cyclist desires a better ignition than the magneto, save only in respect of starting where it compares most unfavourably with the coil and accumulator; the latter gives its best spark at minimum speed, whereas the magneto gives its worst. But if we are going to plump for electric lighting, as seems certain, the situation is perceptibly altered. One and

the same battery-cum-generator outfit may at some future date cater for both ignition and light. When the electrical trade offers us such an outfit, plus its special starting facilities, plus the reliability for which the magneto is famous, we can only make one reply.

For the Cold Stable.

UGH! I have been sampling a sulky engine in a cold stable on an arctic morning with pukka No. 3 spirit—my hoard of 1915 No. 1 having been exhausted. To other sufferers from similar conditions may I commend an injection dope of 50% of methyl ether and 50% of petrol? I believe a rubber pipe from the domestic gas supply is a sound stunt, but, alas! my garage is lit with paraffin, of which the Pool Board No. 3 is already sufficiently redolent.

Leg Wounds and Motor Cyclists.

THE other night I dined with five ex-soldiers, all of whom were ex-motor cyclists with artificial legs. It was an eye-opener to me to learn how walking exhausts such men. One member of the company left Roehampton in 1917, but still finds that a walk of a mile knocks him out on a hot day, and for this reason he has sold out a splendid business in a sub-tropical climate. None of the quintette dares ride a two-wheeler: none of them ever intends to do so again. I am aware that many men with only one natural leg surviving continue to enjoy motor cycling: but the trade should take cognisance of the fact that there are numerous exceptions. They get the wind up for a variety of reasons. The artificial leg suggests an insecure footing, and they dislike handling a mount which cannot stand up by itself. Of course the side-car and the Morgan and the cycle car are available for such men, always provided they can afford the additional outlay. Nevertheless it appears that there may be a distinct, if temporary, demand for something more on the original Carden lines, *i.e.*, the cheap monocar. It is important that the controls should be adaptable for use by men with but one sound leg or one sound arm: I expect the man with an artificial arm feels even more incapacitated for motor cycling than the man with one sound leg. I hope the trade will not leave these unfortunate brethren, who have been crippled in our service, to the chance mercies of their own ingenuity or of agents' adaptations. Most of them have been hit hard in pocket as well as in person, and it is callous to say to a man who formerly pinched to pay £50 for a bicycle, "Oh, you can get the X—cycle car at £150!" We should like to see these men offered a mount they can afford.

The Cone Brake.

A NOVELTY which we are all anxious to try out under road conditions is the cone brake. We had no particular quarrel with the belt rim shoe, so far as use and efficiency went, but it was rather a cumbrous piece of mechanism, especially on chain-driven machines; and we have not the least objection to a brake which is neater, provided it is just as good. The front brake is at present an unsolved problem, and here the cone type may be of special interest. A front brake must not be too powerful, must not be liable to rattle, and must not obstruct wheel removal or tyre repairs. A paper survey suggests that the cone brake should be neat, light, cheap, and self-adjusting for wear. We shall want to be assured that it cannot jam if clogs of mud or small pebbles are flung into it, and that no fresh road for water to enter the bearings is involved. The band brake and the internal expanding type were justifiably moribund before the newcomer appeared. The former could conduct itself with propriety, but was usually a nuisance: the latter suffered from invisibility: the demise of its efficiency was apt to be extremely sudden.

Unbreakable and Unpittable Valves.

THE new steels are going to make minor contributions to our comfort. Exactly twelve years ago I purchased a motor cycle from a leading firm which required a new exhaust valve and new piston rings every hundred miles. In five hours' running on a half-throttle average the exhaust valve scaled away in lumps, and the rings lost all semblance of compression tightness. Things had changed by 1914, but our exhaust valves were always the better for a touch-up when we inspected them, and it was standard practice to carry a spare. Some of the more considerate firms maintained a special sub-section for refacing clients' valves. We took less interest in our piston rings, but nevertheless we noticed that the labour of "turning her over compression" diminished with age. The other day I saw an exhaust valve which had done a hundred odd hours in an aero engine, and barely required skimming before going back for another hundred. This means that there is a possibility of being able to buy overhead-valved engines without fear of frequent hold-ups to hunt for the missing valve head; that valve grinding as a necessary preliminary to any run of length will lapse into comparative desuetude (what a lovely word!); and that there will in consequence be a shade more room in the pannier bag where the spare parts and emergency gadgets live.

A page from a D.R.'s sketch book. A scene familiar to many motor cyclists who have served in France

The Four-cylinder Gonthier Motor Cycle.

Belgium's First Post-war Production.

BELGIAN motor cycle manufacturers are making rapid recovery, despite the troublous circumstances which are still extant, and that they are not behindhand in following the trend of modern design is evident from the production of a four-cylinder machine at Liège, the town whose name conjures up gallant memories of the early days of the war, and which, in pre-war days, was the home of another well-known Belgian motor cycle, the F.N. The designer and manufacturer, who has got so quickly to work, is M. Henri Gonthier, well-known in motor circles in Liège.

The Engine.

The Gonthier engine has four air-cooled cylinders, each a separate casting, and each with a bore of 56 mm. and stroke of 76 mm., giving a total capacity of 748 c.c. It has overhead inlet valves, operated through adjustable tappet rods. The ball bearing nickel steel crankshaft is mounted on three bearings, following car practice. The pistons, which are of a patented type, carry two rings at the top, and beneath the lower one is formed a deep groove, from which a series of holes give communication to the interior of the piston. Oil is collected in this groove, and any excess is passed through to the interior and so back to the crank case. This must tend to economy in oil and reduce carbon deposit without starving the piston and cylinder walls to any particular degree. Lubrication is effected by a neat mechanical pump, designed to maintain a constant level in the crank chamber.

The engine, clutch, and gear box form one unit, being carried in the loop of a duplex frame. The frame is well designed, and of ample strength for sidecar work. The forks are girder construction, with coil springs and parallel action.

A new four-cylinder design by H. Gonthier, a Belgian manufacturer. The bore and stroke are 56 mm. x 76 mm. = 748 c.c.

The clutch is of the plate type, of large diameter, running in oil. The gear box is constructed to give no fewer than seven speeds, with nine gear wheels, of which only two slide on the shafts. It

Near side of unit, showing method of cradling the engine.

is said to be just as simple to operate as a three-speed gear, and yet it provides a fairly gradual progression from low to high, and *vice versa*.

At the same time, it is possible to overstep the intermediary gears and change directly from low to top or otherwise, as desired. The designer describes the gear quaintly as a three-speed gear with two intermediary gears between first and second, and two

more between second and third. A kick starter is fitted.

Transmission from gear box to rear wheel is by a totally enclosed chain. The carburetter, specially designed for this machine, is operated by a single lever and has two jets. The second jet comes into action at high speeds.

The vaporising chamber is said to be particularly effective in atomising heavy fuels. As to the fuel consumption we have no information, but the design bears promise of economical results.

The method of springing, to which this firm is particularly partial, is a parallel motion incorporating large coiled springs; it is embodied in the saddle, front forks, and sidecar springing, and should prove very effective. The question of mudguarding has been well looked after, the guards being very wide and substantially made, the rear guard having formed in it a compartment for tools and forming a carrier.

Both wheels are detachable and interchangeable, and when a sidecar is used a spare wheel may be carried.

As regards the sidecar, M. Gonthier claims to be the first to introduce this attachment into Belgium, and makes a distinct departure from usual practice by employing a pressed steel frame with welded joints. The attachments are particularly strong, and the girder type of stay, also of pressed steel, which stiffens the sidecar axle, is a distinctly good point.

The construction of this sidecar chassis is similar to that of aero engine plates, and since so many of our manufacturers have had experience in this class of work during the war, it is not improbable that it will play an important part in motor cycle construction in the future.

As far as we are able to judge, this machine gives great promise, and, provided that production is not interfered with by the aftermath of war, it should form a sturdy competitor in the four-cylinder market.

The firm, previous to the war, was turning out a very useful $3\frac{1}{2}$ h.p. twin-engined machine, and its production is to be resumed shortly. The cylinders are set at an angle of 50° , and it follows standard practice in other details.

A gracefully designed business sidecarrier supported on a chassis of original design, the longitudinal frame work being of pressed steel.

"SOME BARGAINS."

The Treatment accorded ex-Army Machines between the Port and the "Unfit" Park.

THE CHANGING SEASONS. Ex-Army motor cycles at Kempton Park. Since our recent exposure of the rapid deterioration of these disused machines many have been sold by auction, and the remainder are being removed to repairing depots.

DISUSED Army machines are now under much discussion, and probably many of the impecunious brigade of would-be riders are already visualising their cheap mounts.

Now that D.O.R.A. is moribund it will be permissible to give the readers of *The Motor Cycle* some idea of the treatment meted out to unserviceable machines in their passage through the various collecting and repair depots of the Mechanical Transport, and thus warn many unsuspecting souls of the condition in which they may expect to find most unrepaired Overseas machines.

The motor cycles are despatched from the port of arrival in open trucks, packed cheek by jowl, fifteen to twenty at a time, and, as a result of this, the jolting of the journey and shunting, etc., they present an almost inextricable mass to the men whose duty it is to transfer them on to the familiar 3 ton lorry; this process is not usually effected without sundry ruthless and sudden removals of such projections as handlebars, oil pump handles, foot-rests, and carriers; indeed, it is remarkable how efficaciously "streamlining" may be carried out by means of a viciously-applied "ammunition" boot!

The machines are next dumped (literally!) in an "unfit vehicles" park by a receiving staff, who examine and classify the machines, and also remove the valuable "portable property," such as magnetos, carburetters, and saddles.

It may be that familiarity breeds contempt, or may be sheer discomfort in handling rusty, jagged, broken-backed corks (often under the bitterest atmospheric conditions), which is the cause of much damage, for

if at all refractory or awkward it is no uncommon thing for machines to be flung bodily from the lorries to the ground.

Undoubtedly much of the abuse and man-handling is due to the inefficiency of the arrangements for dealing with motor cycles in quantities, and the men who have no better lifting or transporting tackle than their hands are scarcely to be blamed.

The damage done to machines between the actual moment of becoming unserviceable until the time of entry into the repair shops is not to be conceived by those who have not actually seen and dealt with a consignment of two or three thousand corks, and it is safe to say that the ordinary amateur with a *p penchant* for tinkering who buys a damaged army machine will find his purchase dear at any price.

I do not wish readers to take an unduly pessimistic view of my remarks, but I can state definitely that the majority of machines returned from Overseas during the last two years of the war and repaired in R.A.S.C. workshops have required from £20 to £30 worth of replacement parts, and called for repairs quite beyond the scope of the private riders' capabilities.

Home-service machines naturally are not so often broken up, but one must remember that they are mostly hacks, and are often used and exposed in a manner no self-respecting motor cyclist would tolerate.

Any machines overhauled by the army, and sold in that state would be really excellent value at £10 to £15 below maker's price, as the standard A.S.C. workshops, at any rate, are to turn out machines practically as new—the only danger being the latent possibility of frame breakage.

WHARFEDALE.

MODERNISING AN OLD F.N.

A Sporting Four-cylinder Machine.

The converted F.N., inlet valve side. A dropped tank, disc wheels, and greater rake add much to its appearance.

RATHER over a year ago many of our readers were interested in the F.N. rebuilt by our correspondent "Olivos," and illustrated by a small picture in our Correspondence column. "Olivos" has succeeded in converting this little engine in a most ingenious manner, changing the existing exhaust valves into inlet valves and fitting overhead exhaust valves. Several alterations were also made to the frame, which has changed a somewhat cumbrous touring machine into one with a very sporting appearance.

Valve Arrangement.

The shoulders in the cylinder valve pockets for the old inlet valves were enlarged and a new exhaust elbow was screwed into each. As will be seen from the drawings, these are neat members accommodating an exhaust valve slightly larger than the inlet; in fact, the area of the exhaust port is .886 sq. in., the inlet area being .601 sq. in. The exhaust rocker standards are screwed into the elbows and means are provided for adjusting the clearance between the rockers and the push rods. The rods themselves are shaped something like a golf club, owing to the necessity of locating the inlet tappet rod so as to work through the tubular

exhaust tappet, which somewhat resembles a tappet guide. The camshaft was provided with cams of 220° for the inlet and 240° for the exhaust, and the new cams were placed beside the old ones, the rockers likewise being side by side. The whole arrangement is extremely neat, and takes up extraordinarily little space.

The ingenious arrangement of the inlet pipe should also be noted, while the method of taking the exhaust away from the cylinder heads to the silencer is particularly effective.

Other Details.

Other alterations to the power unit include drilling the pistons, and turning out the flywheel so as to take a dry plate clutch, while an improved form of gear also has been fitted. An under-shield runs below the whole length of the power unit. The rake of the front forks has been considerably increased, which, we are told, has so improved steering that the owner can ride with his hands off the bar, and skidding is quite unknown.

The top tube is now straight and slopes to the under tube, reducing the saddle height and, with the tapered tank, improving the appearance considerably.

Various parts employed in the conversion.

Modernising an Old F.N.—

The weight of the reconstructed machine is about 300 lb. The owner claims that a speed of 55 m.p.h. has been attained, and at an average of 30 m.p.h. remarkable petrol consumption figures have been obtained; on one occasion these worked out at 100 m.p.g., but the average petrol consumption is 70 m.p.g.

Altogether, the machine with its mechanically-operated inlet valves and improved exhaust valves now provides very much better running, especially at slow speeds, the alterations to the flywheel contributing to slower running.

The original cost of the machine was £3 10s. It is now an excellent example of what can be done by an enthusiastic engineer. As an illustration of the versatility of the motor cycle engine, Messrs. Olivos employ a 2 h.p. 1902 Minerva engine to drive machinery in their works. It is adapted to run on gas, paraffin, or petrol.

A sectional view of the converted F.N. engine, showing the overhead exhaust valves and the rockers actuating the inlet and exhaust. The exhaust valve push rod is not shown in this picture.

Another Rejuvenation.

The four-cylinder machine seems to find favour with many riders of a mechanical turn of mind. The photograph of the rejuvenated F.N., which is reproduced below, came to hand last week from Mr. T. C. Garrett, Merton Park, London, S.W., and in this instance it must be admitted that an exceptionally good job has been made of the alteration. The enthusiasm shown by owners for their restored and modernised machines is quite equal to, and generally greater than, that shown by owners of new machines, and probably there is no type of machine that gives the same pleasure as a four-cylinder when running well. Mr. Garrett has not gone to the trouble of converting the automatic inlet valves into the mechanical type, but the several obvious improvements that were made have transformed the old type F.N. into quite an attractive-looking mount of which any owner might be proud.

THE LADY AND THE MOTOR CYCLE.

I WAS not a little astonished the other day to hear a lady remark that to ride a motor cycle was "unwomanly." I had foolishly imagined that all that particular sort of Mrs. Grundyism had died and been buried since 1914, but what one thinks and gives utterance to may find an echo in the mind of others of our sex.

Can a girl ride a motor cycle and still retain every characteristic that is expected of our best young womanhood? I certainly believe so, and my experience and observation covers a period long before the war. There is no coarsening influence incidental to motor cycling, and the only way such can possibly arise is by the rider's deliberate interjection of those elements into the sport. The girl who plays hockey or goes in for basket-ball, for

example, is more likely to get hurt and give way to impulses not exactly lady-like than is the girl who goes motor cycling. Still, many careful parents encourage their daughters to play basket-ball!

Whatever prejudice still exists against the use of the motor cycle by girls is undoubtedly due to lack of knowledge on the part of the objectors. I have found motor cycling a safe, healthy, and ever-fascinating sport, and I feel certain I could bring any biased parent round to my way of thinking in a ten-minute demonstration. So far as the ladies are concerned, motor cycling is just what they make it—and it is so easy to make it simply a pleasant, refreshing, and economical

pastime that I constantly wonder why more girls do not avail themselves of it. The war has, of course, brought countless recruits, but as one who is heart and soul in the pastime I want to invite and convince its detractors, the majority of whom, I fear, are, as in so many other cases, those who know least about it. There is room for us all.

MADGE.

An F.N. owned by Mr. T. C. Garrett. The machine has been partly reconstructed and a new tank fitted. When first purchased its petrol consumption was 40 m.p.g., but by fitting and experimenting with the A.M.A.C. carburetter a consumption of 90 m.p.g. was obtained.

WORK FOR THE CLUBS.

Reminders from Men in the Movement. Revitalising the Pastime.

*By Lt. W. Cooper, who first suggested
the Winter Trials.*

ALTHOUGH the time is fast approaching for many of the boys to be on the open road again, are our club organisers and secretaries ready with their reconstruction programmes?

There is not the slightest doubt there is going to be a wonderful boom in motor cycling club life, and, in order to keep up enthusiasm for the keen members, new competitions must be inaugurated.

Why not revive the Blackpool, Brighton, Saltburn, and Skegness speed trials?

Two of the most successful speed events in the management of which assisted were the Streatham and District M.C.C. open speed trials during 1913 on the Madeira Drive, Brighton, and the Essex M.C.C. speed event, 1914, at the opening of the new promenade at West-cliff-on-Sea, the latter being witnessed by over 10,000 spectators.

Races might be arranged between a fast 500 c.c. pre-war model and a 500 c.c. reconstruction model, and I know of at least two machines which will be able to give the latter a run for its money. Many readers may remember the speedy Matchless-M.A.G. at Westcliff and Doncaster.

Then we have the eight-valve Indian, M.A.G., and Harley-Davidson racers. Is it possible to arrange an event to compete against these foreign giants? A trial for ladies only might be included (many of the fair sex are keen to compete against all comers), whilst many of our speediest despatch riders will be home and anxious to test their riding and driving abilities against the fastest of our cracks. What a time it will be for Stanley (Triumph), Bailey (Douglas), Emerson (A.B.C.), O'Donovan (Norton), Collier (Matchless), and many others.

What club secretaries want to avoid is the irksome 20 m.p.h. split second timing. I suggest that a competitor's time should be taken from his own watch, which might be sealed in a small tin box and fitted with a glass lid.

Another important point to remember is that clubs should encourage the trade man, or at least include in their programmes events for the "trade," maintain that no large club can survive without assistance from the trade. I have a great admiration for the trade rider (and I have competed and ridden many thousands of miles against the best of the trade), and have always found him a gentleman and sportsman of the highest grade, always willing to assist an

Lieut. W. Cooper.

"unfortunate" in distress irrespective of the make of machine on which he is competing.

That gallant sportsman the late Rear-Admiral Sir R. K. Arbuthnot was never so happy as when competing against the best of our trade men, and that is why I am so emphatic about encouraging the trade.

This is the period of reconstruction, and among the many things which have to be built up again are the motor cycling clubs, and the Armistice was scarcely signed before the more energetic ex-clubmen were thinking of competitions and the clubs of the future. In the following four short articles some interesting opinions on this subject are given by four well-known clubmen who in the past have worked hard to encourage the competition and social side of the pastime of motor cycling. We take this opportunity of inviting secretaries to write us concerning the present position of their clubs.

The important trade events can be left in the capable hands of that progressive body the Auto Cycle Union, whose energetic secretary, Mr. T. W. Loughborough, has already outlined in *The Motor Cycle* the Union reconstruction programme.

Shall we see during the reconstruction that popular "social" club the Motor Cycling Club, Ltd., affiliate with the A.C.U.?

*By Mr. J. Simmonds, Hon. Secretary
East Midland Centre A.C.U.*

MOTOR cycling, after its period of quiescence, should again prove itself the premier sport. Have not the airmen—our supermen—told us that nothing can vie with it? Was it not the sport of pre-war days that gave our splendid motor cycling boys the training in nerve, pluck, and endurance, fitting them instantly for the branch of service to which the majority instinctively turned, the Royal Flying Corps? Was it not to an unassuming motor cyclist, a fellow club member, the late Capt. A. Ball, that belonged the glory of winning, I believe, the most, certainly the highest of fighting honours during the war? May not motor cyclists as such do something to perpetuate his memory?

The first time awheel, one will naturally turn one's course to the scenes visited in times gone by, where happy clubmen congregated. The old trial courses will be revisited, the various disasters and brilliant performances of fellow clubmen will be recalled. How vividly we cannot

tell. Already certain hills, each with its particular incident, are indelibly stamped upon my memory, hills that for me will be eternal monuments to the memory of gallant men who have made the great sacrifice.

To the future we look with the greatest hope, both from the sporting and social point of view. As the various clubs in the adjoining counties are again brought into being, arrangements will be made to reinstitute the inter-club trial for the East Midland Centre Challenge Cup. New clubs will be especially welcome, and help gladly given in their formation. No town or village in the East Midlands having half a dozen riders should be left unrepresented. Arrangements have already been made by a few enthusiasts to visit various towns in the East Midlands. A communication from intending club promoters to me at 10, Cranmer Street, Nottingham, will ensure a personal visit from one of our committee to ensure their inclusion in the inter-club events arranged for the coming season.

The question of the banding up of all affiliated clubs into geographical centres should again be taken up by the A.C.U. No difficulty should be found in forming a geographical basis; the only difficulty lies in placating a disgruntled club on the fringe of two centres, one of which I know would rather plough the lonely furrow than join in a centre on the fringe of which it is geographically placed. Mr. Straight, the late secretary of the A.C.U., was keenly interested in the centre matter, and visited Nottingham to form the East Midland Centre, since which time no other centre appears to have got to work, the fault lying mainly with club secretaries themselves. Mr. Loughborough also came to Nottingham in 1914, and outlined a scheme which no doubt will again be brought forward. What we in the East Midlands desire is a national club trial, eliminating rounds to be run off in each centre. The first, second, and third teams to represent their centre in a final from north, south, east, and west. The restriction of entries to about three teams each would prevent the trial from being unwieldy—a fault that was growing far too common. That such a trial could be run is proved by clubs being drawn from great distances in the popular *Motor Cycle* cup competition, which grows more unwieldy year by year, the main cause of such popularity being the great publicity given to it in the pages of *The Motor Cycle*, while trials secretaries of smaller clubs when running a trial are

Lieut. W. Cooper.

Mr. J. Simmonds'

Work for the Clubs.—

restricted, no doubt by reason of the number of weekly competitions of a similar nature, to a comparatively brief paragraph. This is a matter that club secretaries must get remedied.

Reverting to the centre trial question, the trial, if arranged, would be a means of drawing a large number of clubs to the A.C.U., who, by its influence, can command the publicity of the motor cycling press. With the funds at its disposal a trophy and gold medals could be awarded—medals as awarded in *The Motor Cycle* cup competition (which is run free from trade organisation)—medals clubmen would be proud to wear.

By Capt. S. Chas. Perryman, R.A.F.,
Hon. Secretary, Birmingham M.C.C.

AT the moment of writing I am still the hon. sec. of the Birmingham Motor Cycle Club, but for the present am stationed away, and am unable to attend a general meeting of the members which has been called to elect officials for 1919. This is sufficient to show that the Birmingham club is alive and alert and only waiting an opportunity to resume all its old activities. I hope to be closely identified with the fortunes of the club for many years to come, and to assist in the organising of many another Birmingham-Land's End, Birmingham-Carlisle, and Birmingham-Edinburgh run, also in the running of the "Midland

Cup" and the open passenger machine trials, which were so successful before the war upset all our plans. It will be difficult, I think, to initiate any form

Capt. S. C. Perryman.

of trial which will serve the purpose of a sporting test for both machine and rider better than did the pre-war reliability trial, with, of course, the T.T. race as the principal test of the year. International trials or competitions should be fostered. Undoubtedly trade follows the competition, and it should be found possible and worth while to foster and encourage entries from Continental, Colonial, and American riders in our home trials, and to send entries to foreign competitions.

I should also like to see a large development of the inter-club trial, and would put in a plea for a fuller and freer social intercourse between the local clubs of a district. A lead in this direction is being made by the clubs located in the Birmingham district, who are preparing a great reception for the "boys" from the Front on their return. This should be a great event, and is an assured success from the beginning. The idea is one worth following, for undoubtedly the

"motor cycle" and "transport" men, not to mention "tanks," have done some of the best work of the war—work which will merit every scrap of recognition accorded it.

By Mr. Harold Weldon, Hon. Secretary,
Nottingham and District M.C.C.

IT is obvious to all seasoned riders that the only real test and guide to the buyer is the Six Days Trial. This being so, would it not be better for the A.C.U. to concentrate upon it, and leave the one-day trials to the centres or the affiliated clubs? I am of the opinion that half the value of these trials is lost through no record being kept of the quantity of petrol and oil used. The quantity used would probably have been rather startling in the case of certain 11.9 h.p. so-called cycle cars which have competed. Of course, this would create more work for the organisers, but if the way of running were reverted to in which a start is made each day from a different town, the local clubs would help. In fact, they could be made responsible for checking, supplies, accommodation, etc., when the trial passed through their territory. It would certainly create more interest in the local clubs, which is what we want.

Mr Harold Weldon.

A BICAR OR TRICAR AT WILL.

A Remarkable Vehicle designed by an American.

THE laws of evolution are governed by demand. Inventors sometimes forget this, and, instead of devoting their time and ability to producing articles for which there is a certain demand in the immediate future, they get so carried away with their ideas that eventually they reach a point where their inventions border on the ridiculous. The invention illustrated here is in this category, for it is difficult to imagine a vehicle such as is depicted having the least appeal to the motorist, while even the "crank" would hesitate before paying good money for an article so ambitious in character and so complicated in construction.

It is not our intention to give a lengthy description of this brain storm: it is submitted to readers of *The Motor Cycle* only to show to what extent it is possible to stretch the inventor's brain when he becomes possessed of an ingenious idea.

The Object?

The object of the invention is to provide a motor cycle normally operating on two wheels, but capable of being converted while in motion into a three-wheel vehicle of "inherent equilibrium." The front wheels are movable away from and toward each other while the vehicle is in motion at the will of the driver. By means of an electric switch, this movement of the wheels is made to operate automatically at certain speeds.

To explain how this is done the inventor's claims cover over ten pages of

Three of the several drawings in the patent specification which describes the bicar-cum-tricar referred to here.

a patent specification paper, with nearly 7,000 words and upwards of 200 figures. It will be appreciated, therefore, that to attempt a description here is hopeless.

It will be observed that the vehicle is depicted as having a four-cylinder engine, shaft-cum-chain transmission, a rigid frame with a sprung body, wheel steering, etc. The main feature of the design, however, is the folding front wheel arrangement. When used as a bicycle the front wheels are close together, side by side, and approximate to a twin wheel. By electrically-controlled mechanism in the steering head and the back wheel these wheels are made to spread out when the machine drops below

a certain speed and to close up again when that speed is exceeded. Steering a bicycle with a "twin wheel" is a rather uncomfortable thing to contemplate, while the automatic change over probably would be a little nerve-shaking. The illustrations are some of the many given in the patent specification, and include an elevation and plan of the vehicle and a diagram showing the mechanism in the steering head. If any reader requires further information, the number and date of the patent specification is 17,220, July 11th, 1918.

What shall we wear?

THE PROBLEM CONFRONTING THE LADY MOTOR CYCLIST.

"**W**HAT shall I wear?" is popularly alleged to be one of the most absorbing topics to the feminine mind, and to the proud owner of a first motor bicycle it is only second in importance to the question, "What shall I ride?" In this case it is not vanity, for a sensible garb makes all the difference to the lady motor cyclist's comfort.

For myself the matter presented some difficulty; if I had ridden only to please myself I should have had no hesitation in wearing the smart free costume of the land worker and riding triumphantly arrayed in a threequarter coat, knickers, and leggings. But I did not ride to please myself. I rode on business involving the credit and standing of other people (as so many women will now the war is over), and I had to deal with all kinds and classes, from retired colonels to middle-aged ladies with parrots and pug dogs. Somehow, I did not fancy that they would appreciate the land workers' costume.

My thoughts next turned to the fascinating suits that I had seen described in back numbers of *The Motor Cycle* arranged to meet this difficulty by an ingenious device that converted them into knickers when riding and into Bond Street walking skirts when off the machine. I investigated these fairly thoroughly, but finally rejected them because (1) I had a friend who had a friend who was alleged to look a "sight" in one, (2) they were expensive, (3) I saw no reason to believe that they would keep clean in all weathers, and (4) I did not think that

I should be warm enough. Nice as these skirts are, I have never regretted my decision.

My final choice was as follows, and I commend it to other women riders, who will no doubt despise it as quite unequal to their own.

1. My first layer of clothing consists of the land workers' costume borrowed from a young sister. I should not have bought this, but it has been invaluable, for being mackintoshed it affords protection from wet. It also has capacious pockets that carry my various licences, a large knife, and a small "King Dick" spanner from which I am never parted. It has the further advantage that its colour is inconspicuous, and that when I know I am rid of my censorious world I can cast my outer garments into the sidecar and ride as free as any despatch rider. I might add that underneath the land workers' costume I wear a double set of underclothes. The English climate is a cold one!

2. Over the land workers' knickers, but under the coat, I wear an old blue serge skirt. This

also cost me nothing, as it was destined for a jumble sale until the motor bicycle rescued it. It is a concession to Mrs. Grundy that I bitterly resent, but I have found that my moral courage is not sufficient to enable me to be quite unmoved at the jeers and hoots of small boys when I walk down a village street unaccompanied by the motor bicycle.

3. Over all this I wear an ordinary length mackintosh that cost me £3 10s. When

Breeches and puttees form a serviceable but rather clumsy costume for the lady rider.

What Shall we Wear?—

first bought it was very fine and looked well, but since I sat in a pool of petrol and knelt in a mixture of tar and oil it no longer does me credit, but at least it bears the marks of its trade and has many years of useful service still left in it. Round my waist I have an ordinary leather strap, stolen from a bicycle carrier. Once I bought myself a fancy plaited leather one—very smart and up-to-date, but the pressure of underclothes burst it apart on my first ride, and it now lies by the wayside unless it has been picked up by some less corpulent rider than myself.

4. On my legs I wear, first, strong golf boots that come half-way up to my knees, and over them either leather gaiters reaching to the knee or long rubber leggings, made by J. B. Brooks and Co., reaching to the thigh; price 16s. 6d. The seller tried to induce me to believe that ladies only needed the shorter leggings, but sad experience in the rain on a push bicycle with a cold pool of water sitting, like a corpse, on my lap had taught me that there is no part of the cyclist that needs more protection than the region above the knee.

5. My head was my greatest difficulty. At first I cherished ambitions that I should be able to look like an ordinary human being when motoring, and bought myself a small close-fitting straw hat and an ordinary veil.

A mixture of dust and rain soon played havoc with this, and I was reduced to various makeshifts. I found that I was quite unable to keep on my head the neat hats that other women wear, though I have never been able to discover the reason for this, so I purchased an old-fashioned motor bonnet, tied with a piece of ribbon under my chin. It never comes off, rain does not hurt it, and it keeps my ears warm, so

The ordinary masculine overalls cannot be said to be a becoming dress for a girl, but some detachable leg covering is desirable when a short coat is worn.

in spite of the somewhat fantastic appearance that it gives me, I cling to it faithfully, though I carry an ordinary hat in the sidecar to meet any crisis that may arise.

6. Protection of the hands is one of the greatest problems, and I have not yet solved it satisfactorily. They become so cold that I am unable to sound the horn, and I dash recklessly through crowded streets, thinking that a hospital would, at any rate, be warm. I bought a pair of strong leather gloves, price 8s. 6d., under which I wore woollen ones, but I suffered agonies in cold weather and developed lamentable chilblains. My latest discovery was a pair of airman's "bags," i.e., leather mitts, lined with lamb's wool, that had

been left on the hosier's hands as being too small for the average aviator. These cost 14s. 6d. Their only fault is that they are short and leave a hiatus between themselves and the sleeve, but this has been met by a pair of woollen wristlets. I can now warm my chilled fingers by curling them inside each other in the mitt, and only my thumb suffers acutely. The mitts are clumsy to use, so I keep them for the coldest

weather. The hand problem is still to be solved.

7. My only other item of clothing is a black silk navy handkerchief—a present—round my neck. During my first really wet ride a cold stream of water trickled slowly and persistently down my neck until it had formed a little lake dammed up by my leather belt, which sent me hurriedly to bed upon arrival at the village inn. Since then I have learnt better.

My total clothes bill, then, stands as follows:—

Mackintosh	£3 10 0
Gloves (8s. 6d. and 14s. 6d.)	1 3 0
Bonnet	13 0
Leggings	16 6
Total	£6 2 6

This does not seem unreasonable for the warmth and comfort afforded.

(Miss) E. M. GARDENER.

THE MOTOR CYCLE AND THE INDUSTRY, AS SEEN BY "THE TIMES."

"THE motor cycle is abominably and unnecessarily noisy," writes an author of an article in last week's *Times* who compared the 4 h.p. 2 cwt. two-wheeler "barking like a dog and arousing a whole neighbourhood" with "40 h.p. and 2 tons weight sweeping past . . . full of stateliness and with little audible effort. . . ."

The writer goes on to show the extraordinary conservatism of the industry in the past, stating that "the two-wheeler . . . is inclined to be the produce of the cycle mechanic rather than the engineer. This state of affairs, however, will rapidly change now that important and powerful firms are taking charge of its interests."

This statement appears to be quite unwarranted, and the reference to important and powerful firms taking charge is erroneous and unfair to the British motor cycle industry.

"No one can pretend," says the writer of the article, "that the motor cycle is half as good as it ought to be. The provision of good suspension, so that it can be ridden fast over bad roads without discomfort, the reduction of weight, so that C₃ can handle it as easily as A₁, quietness of running, simplicity of control, adequate protection against mud and dust—all these might be incorporated . . . without in the least making it any the less a 'sporting' vehicle for the enthusiast."

SPARES AND SERVICE.

Some Remarks on the Supply of Spare Parts in the Past and in the Future.

THERE is no motor cyclist of any lengthy experience who has not had trouble in obtaining some spare part for his machine. This is a statement of truth, but it ought not to be. The technical press is always containing some grumble, more or less serious, of the way in which an unhappy reader has been treated in an attempt to get some quite simple part from the makers of his machine; and in a quite recent issue there was a paragraph to the effect that a correspondent had had to wait a whole week before he received any acknowledgment of his letter asking for a simple fitting to be sent to him as soon as possible, as his machine was held up and out of action pending its arrival. When the acknowledgment did arrive it was no more than the usual *pro forma* invoice, which in this particular case told a tale the laggard makers might have wished to deny—namely, that the part *was* in stock, and that the cause of the delay could be no question of difficulty in obtaining material or labour. Why is this, and must it always be so?

Need for Reform.

At the present time we are all prepared to make allowances for prevailing conditions, but really these conditions have not made as much difference as is often alleged, simply because things were so bad before the Hun claimed our undivided attention that they could not become much worse. Complaints on this matter have always been more frequent than on any other, and they cannot all have been due to the unreasonableness of correspondents. Some firms have been conspicuously better than others—not that this need mean a great deal—while some have been quite good, but they both belong to a very small minority, of which the most conspicuous members have always been the Americans. Who ever heard of a serious complaint about an American firm as regards its supply of spares to a stranded rider of one of its products? Of course, the cynic might say that practice has made perfect, and that this is the explanation why the American spare part service has always been so good, but obviously the argument will not hold water. Are English firms always to allow their greatest competitors this pull over them, and are they never to make an effort to retrieve the situation and to regain such markets as they have undeniably lost through this matter alone?

A Very Welcome Innovation.

Fortunately, signs are not wanting that in the motor cycle world the real necessity of some reform in this direction is being recognised. One of the most progressive programmes is that of a new concern in the

Suggestions to Manufacturers regarding Service.

motor cycle field. Rumour has it that one of its strongest selling points is to be its spare parts service. A depot is to be opened in London for the supply of spares, and it is to be kept open night and day, and any spare is to be despatched immediately by passenger train on receipt of a request by telephone or telegram!

Whether rumour is more reliable than usual or not, there is here food for serious thought by the *pro forma* and weekly mail specialists. As to the details of the payment system which these people have in mind I can say nothing, but obviously difficulties of this nature can be overcome, and it would appear that here is an example in which they have been removed entirely. If every other plan failed it might almost be worth while for a firm to put, say, £2 or £3 on to the price of its machine so that the purchaser would have a balance with the firm on which he might draw in case of emergency. Many riders would willingly pay this sum when it was incorporated in the cost of the machine, while they would be reluctant to open a ledger account with the firm by the handing over of the £2 or £3 as a separate sum soon after taking delivery of the machine. And as the sum would be connected in the mind of the firm with the machine of a particular number, there is no reason why the selling of the machine by its first purchaser should not also carry the claim to the deposit to the new owner, who, of course, would be able to draw on it only by means of obtaining spares; and so it would go on until some owner would receive notification that a spare he wanted was barely covered by the deposit standing to the credit of that machine. He could then renew the deposit or allow it to lapse, and the alternative that he chose would provide conclusive proof as to whether the idea was appreciated sufficiently to justify its continuance or not.

Standardisation of Parts.

If for some reason this suggestion were to prove unworkable it does not by any means follow that other simple means could not be found to improve our spare parts and replacements service. It has been suggested that it might pay works to run their spares and even repair departments at a loss, and a little thought should make it clear that the idea is in no way reminiscent of absurdity. Presumably, no section of the Ford factory is run at a loss, but how many Ford cars are sold in the course of a year as the result of the well-known Ford service? Who has not heard a Ford owner say that he would prefer an English car, and would not mind the extra capital outlay if he could only be certain of getting the spares he might require as promptly and *comparatively* as cheaply as he can in the case of the Ford?

Spares and Service.—

Cheapness of parts is a very important factor, but it is not the only one to be considered. Manufacturing methods that have made a pair of motor cycle handle-bars dearer than a new Ford steering column have to go by the board, and they are going—or if they do not the industry as a whole will show them the way—and when those little parts such as brake fittings, engine valves, etc., are so much more cheaply made they will also be more plentiful, and as a result of standardisation less varied in shape and size. So that their distribution will be simplified and easily extended. Thus we may in time become less dependent on the makers for the supply of many minor parts; and which of us has not suffered, at some time

or another, from going into a garage for a small spare for our machine to find that the proprietor has plenty of Jones's but none of Brown's, and, of course, only the latter will fit our particular 'bus? The occurrence of this kind of thing stands every chance of being much lessened in the near future, and it will be to the good of the pastime as a whole when it can be obviated altogether.

Taking things all round there is nothing that the pastime of motoring, and especially of motor cycling, so much requires to widen its popularity enormously as a much improved spare parts service, and it is a more than welcome sign that there are indications that this improvement is on its way to us. May it come quickly and stay long.

RAMA.

MORE NOTES ON SPRING FRAMES.

The Suspension Problem as seen by an Engineer.

BEING a mechanical engineer with considerable motor cycling experience, the articles on spring frames in recent issues of *The Motor Cycle* "gave me to think." I cannot but gather from some of the designs that their originators have scarcely given sufficient attention to what I may term the "incidental mechanical" requirements of a spring frame.

Fig. 1.

Fig. 2.

For the purpose of these notes I will neglect those designs that aim only at the "insulation" of the rider, as I consider that they may be regarded, as it were, steps towards the ultimate goal of fully-sprung machines, useful steps though they may be.

The basic requirement is, of course, the interposition of some form of spring device between the wheels and the main frame of the machine. The incidental requirements from a mechanical point of view may be cited as follows:

- The maintenance of the wheels in the plane of the frame of the machine.
- True triangulation, as far as possible, of the added links and framing.
- Resistance offered to the thrust of the rear wheel in such a way that the oscillations of the wheel take place along an arc, the centre of which is at or near the centre of the driving chain wheel or belt pulley—this in order that the vertical movements of the rear wheel may not vary the tension of the chain or belt.

As an illustration of these points, fig. 1 shows a very old form of front wheel springing, which fails to fulfil

requirements A or B, whereas fig. 2 shows a front wheel springing which fulfils both requirements in addition to forming a simple, pleasing design, easily kept clean, as the spring is enclosed in a telescopic sheath. It would be an improvement were the mud-guard attached to the forward forked member instead of the rear member.

Again, one wonders why the A.S.L. frame construction was not arranged on the lines of example fig. 2, for as the A.S.L. stands it fulfils neither requirement b or c, which the other does.

It is worthy of note that those types incorporating a pivot in the rear horizontal stays in the neighbourhood of the countershaft gear box should have the pivot bearing as long as possible, as the rigidity of the frame in a lateral direction is dependent on this joint; this is particularly the case where leaf springs are introduced under the saddle, as in the Raleigh, A.B.C., Indian, etc., where the additional support given laterally by the down stays is not usually supplied by the method of attachment of the leaf springs.

I imagine that coil springs may have to be of considerably larger diameter or greater length than at present employed if they are to give all the results of leaf springs. With limited space, as in the Brough, N.S.U., etc., I am of the opinion that the introduction of leaf springs as shown in fig. 3 would result in easier riding than would be obtained as at present.

I trust that my citing a German example (the N.S.U., fig. 2), and my criticisms of the other types mentioned, may not incur the displeasure of our designers, to whom all credit is due for trying to provide what is required by riders of present-day motor cycles.

T. SHARRATT, LT.

B.E.F.

Inspector of Ordnance Machinery.

Better Equipment.

There is a tendency among manufacturers to supply their new models with better equipment, such as saddles, tool bags, and tools.

New Index Mark for Middlesex.

In addition to the distinguishing index marks, H, MX, MC, which designate motor vehicles registered in the county of Middlesex, there has been issued to the council the letters MD.

A Famous Track Rider's Post.

We learn that Mr. D. R. O'Donovan, in addition to his duties of supervising the Norton "Brooklands Special" engine department and the Brooklands tests, is head of the experimental engineering department.

French Government Machines.

We hear that the French ex-Army vehicles are receiving approximately the same treatment as are ours at Kempton and elsewhere. The trouble in this case is shortage of labour apparently, as many of the vehicles are lying in trucks and waggons. Whether they would be better off in the sea of liquid mud which prevails in the locality is a moot point.

Motor Cycles in Belgium.

Two of the principal Belgian motor cycle firms, F.N. and Saroléa, are in a bad way, as the Huns have carried away most of the tools and material from the factories. The former factory has suffered particularly severely in this respect. Not only have the machine tools been taken away, but the foundations on which they were built have been absolutely demolished. The only manufacturer who is able to resume the building of motor cycles is M. Gonthier, who has a four-cylinder motor cycle, with which we deal in this issue.

Many private motor cyclists had their machines requisitioned by the enemy, consequently there is a good demand for motor cycles, though Belgian agents for English machines are not in a position to supply, owing to their being unable to secure delivery, but it seems evident that those British firms which are not represented might take steps to become established in that country. They will receive considerable assistance from the Editor of *La Moto*, 1, Rue du Convent, Brussels, Belgium, who will be glad to receive catalogues of new models.

Fifteen Months in Hospital.

We have heard this week from Mr. W. (Billy) Pratt, the well-known competition rider, who, we are sorry to record, is still in hospital, where he has been for fifteen months, after being "knocked out" at Arras. He is looking forward to the time when he will be on the road again. We hope the date is not far distant.

The 8 h.p. British Excelsior.

The specification of the Excelsior sidecar has now been decided upon, and includes 6 or 8 h.p. J.A.P. engine, M-L magneto, B. and B. carburetter, three-speed Sturmey-Archer countershaft gear, totally enclosed all-chain transmission (Hans Renold $\frac{5}{8} \times \frac{3}{4}$ in.), quick detachable interchangeable wheels, made under licence from Lea and Francis, Ltd., provided with Timken roller bearings, Druid Mark II. fork, semi T.T. bars, 25 in. wide, 28 x 3 in. Dunlop heavy-studded tyres, Best and Lloyd drip feed, stands to front and rear wheels. Ground clearance 6 in. The sidecar has an under-slung chassis, with interchangeable wheel and four-point attachment, and coach-built body. The prices are to be £120 for machine only, £150 with sidecar; Lucas dynamo lighting set £25 extra.

A Radial-engined Cycle Car.

Mr. A. H. R. Fedden, who has for many years been associated with high speed internal combustion engines, has designed a cycle car chassis with a three-cylinder radial engine of 994 c.c. capacity. The vehicle will weigh 6 cwt. complete, and, it is said, should be possible to produce to sell at £160. The bore and stroke are 75 x 75 mm., and the b.h.p. is 16 at 2,000 r.p.m.

Second-hand Prices.

Average prices as advertised in *The Motor Cycle* of January 23rd and 30th:

	Previous to 1914.	1914 and 1915.	1916.	1917 and 1918.
A.J.S., 6 h.p., sidecar	—	£76	£140	£142
B.S.A., 4½ h.p., sidecar	—	£55	£69	£85
Calthorpe, 2½ h.p.	—	£27	£33	—
Douglas, 2½ h.p.	£23	£40	—	—
Enfield, 3 h.p., twin	—	—	£48	—
Indian, 7-9 h.p.	—	£51	—	—
Indian, 7-9 h.p., sidecar	—	£69	£87	—
Matchless, 8 h.p., sidecar ...	—	£98	—	—
Norton, 4 h.p., sidecar	—	—	£84	—
P. & M., 3½ h.p., sidecar	£38	£63	—	—
Premier, 3½ h.p.	—	£36	—	—
Premier, 3½ h.p., sidecar	—	£39	—	—
Rover, 3½ h.p.	—	£37	—	—
Rover, 3½ h.p., sidecar	—	£47	—	—
Rudge, 3½ h.p.	—	£34	—	—
Sunbeam, 3½ h.p.	—	£66	—	—
Triumph, 3½ h.p.	£27	£41	—	—
Zenith, 1 h.p.	—	£40	—	—

DEMILITARISED. The rider of a Triumph countershaft model aiding in the rapid dispersal of the demobilised. The naval man who has just received his papers is evidently no stranger to pillion riding, judging by the weighty kit bag he has to balance.

Running Order?

In last week's issue we noted the following advertisement: Rex $3\frac{1}{2}$ h.p., in running order; less mag.

An Unpuncturable Tyre.

Mr. F. L. Rapson, the inventor of the Rapid jack and other car accessories, has produced an unpuncturable tyre, which appears to have great promise.

Embargo on Imports.

The Autocar states on good authority that the prohibition on foreign motor imports will probably be cancelled soon, but a tariff of 33½% may be retained.

United Action.

Successfully to combat repressive measures concerning taxation, fuel, and roads, a united front must be presented on the behalf of all private motorists. Every motor cyclist should join a motorising organisation, and all such organisations should work together for the common end.

Ixion Models.

The Ixion Motor Manufacturing Co. has now issued its 1919 prices and particulars of its "Peace" models. These include a single gear two-stroke at £42, a similar model with two-speed countershaft gear at £50, a lady's model at £56, and a sidecar at £68 10s. The last-mentioned outfit is more than a two-stroke lightweight with sidecar attached; it is designed throughout as a sidecar outfit for those to whom very high road speeds are not essential. It is fitted with a two-stroke engine having a bore and stroke of 75 and 79 mm. respectively, a Starmey-Archer three-speed gear, with kick starter, and tyres 26×2½ in. The lugs for sidecar connections are not detachable from the motor cycle frame, and to detach the sidecar occupies about three minutes only.

Nuremberg to Coventry in Two Days.

After an absence in Germany and Austria of more than five years, Mr. Basil Vickers-Jones, ex-T.T. and competition rider, has returned to England to re-enter the British motor industry. Before the war Vickers-Jones was with the Premier Co., and the last time he visited England was to demonstrate the company's light car, produced in their German works. Mr. Vickers-Jones completed the journey—a distance of approximately 700 miles—in forty-eight hours.

At the time the war broke out, Vickers-Jones was at the Premier Co.'s Eger (Bohemia) Works, and was interned in a village far removed from the war zones. In fact, he tells us, he did not hear a gun fired until his return to England, and did not see a war aeroplane until two weeks before the armistice was signed.

Mr. Basil Vickers-Jones, ex-T.T. and competition rider, who was interned in Austria during the war.

THE DISPOSAL OF ARMY MOTOR CYCLES.

It is expected that the Government's decision concerning the disposal of war-worn motor cycles will be announced almost immediately.

At two sales in London last week, a further number of machines were sold, and obtained high prices. It is fairly obvious that these sales have some other object than the disposal of surplus Government property, and it is suggested that they are being held merely to "feel the market."

In the meantime, the negotiations with the Association of British Motor and Allied Manufacturers are still proceeding. Taken generally, the "trade" would like to overhaul and repair these machines before they are offered to the public. This does not, however, necessarily mean that makers desire to repurchase machines for resale, but may act as repairers and selling agents for the Government.

Benzole Tax Rumour.

At the time of going to press, there was a report that the Government had decided to impose a tax of 6d. per gallon on benzole if the British benzole producers continue to sell their output, or any portion of it, to the petrol companies.

North Country Coast Road Threatened.

The coast road from Silloth to Maryport is threatened with extinction, by being converted into a track for a light railway.

An All-British Composite Car.

In this week's issue of *The Autocar*, on sale to-morrow, there is a fully illustrated description of a new car produced by Messrs. Angus Sanderson and Co., Ltd. (the parent company controlling the N.U.T. firm), Messrs. E. G. Wrigley and Co., Ltd., and Messrs. J. Tylor and Sons, Ltd. The first year's output is expected to reach nearly 10,000 cars.

Benzole.

The present position of the average benzole producer is that he cannot sell to the motorist on a large scale without the aid of the distributing facilities of the petrol companies. The Government is understood to have recently offered to control and distribute the fuel through the Anglo-Persian Oil Co., a controlled establishment. This offer has been rejected, owing, it is said, to the opposition of several firms who had arranged with the allied petrol companies to use their distribution service.

It is rumoured that the petrol companies have made a very tempting offer to the British benzole producers, and if this is accepted the former concerns will have control of the only competitor to petrol. This will mean that motorists will have to pay for fuel just what the petrol companies like to charge. In other words, the whole fuel supply of Great Britain will be in the hands of a monopoly. Such an unfortunate state of affairs must be avoided at all costs.

A Sale of Surplus Government Motor Cycles.

A sale of Government motor cycles was held at Aldridges, St. Martin's Lane, London, W.C.2, on the afternoon of the 29th ult., and very high prices were obtained, notwithstanding the fact that some of the machines were without saddles, and others looked very much the worse for wear. Five Zenith motor bicycles brought £54 12s., £45 3s., £43 1s., £42, and £37 16s. respectively; five Ridges were sold at prices ranging from £42 to £46 each, while some Sunbeams fetched £59 17s., £58 16s., £51 9s., £43 1s., and £42. The sale was very well attended.

On the following day forty-two Government motor cycles were sold by Messrs. W. and S. Freeman (Aldridges). All except two were Douglasses. The first machine, in very poor condition, went at 29 gns., the average price for the whole being about 26 gns. The machines were not described in detail in the catalogue, and many were in an exceedingly poor state. The highest price paid for a Douglas was 37 gns., and on examination of the machine it was found that the frame was broken just under the steering head.

Somebody got a remarkable bargain in Lot 135. The auctioneer described it as "A Douglas motor cycle, registration L.R. 1905," when someone shouted "It has no engine!" The result was that it was sold for 15½ gns. It transpired, however, afterwards, that it had an engine, and, considering the condition of the other machines put for sale, it was in a very fair state, and was consequently ridiculously cheap.

Two Douglas machines without engines fetched 7½ gns. and 10½ gns. respectively, while a Douglas frame and wheels went for 11½ gns.

Bidding was exceedingly keen for a three-speed countershaft Triumph, the only one of the batch which had been ridden to the place of sale. Bidding started at 30 gns., and the machine was finally sold for 44 gns. The handle-bars were rusted and covered with verdigris.

Despatch riders with the Army of Occupation whilst passing through Liege. Sgt. Haskins (on right) says that the troops have been joyously welcomed, and the inhabitants cannot do enough to express their gratitude. He was at St. Quentin when the Germans came through, and, "although over fifteen stone, failed to stop them."

The Latest Information regarding the Revival of the Various Clubs.

Westmorland M.C.C.

It is expected that this club will be going strong by early summer, though, at present, the majority of the members are in the Services. The hon. secretary, Mr. Joseph Wright, Blackhall, Kendal, is keeping an eye on things, with a view to early resumption of activities.

The Motor Cycling Club.

The annual general meeting of the M.C.C. was held on January 29th. Considering the difficulties of the times, the meeting was well attended.

Col. Jarrott was re-elected president with acclamation, and the following vice-presidents were also re-elected: Messrs. Albert Brown, R. C. Davis, E. B. Dickson, A. J. Jackson, J. Van Hooydonk, and Ernest Perman. Mr. W. H. Wells was re-elected captain. Mr. Southcomb May is carrying on the post of hon. secretary, which he filled so ably prior to the war. Maj. Baddeley, M.C., was re-elected hon. treasurer, and Mr. W. Richards was re-elected auditor.

Mr. Head, the chairman of the committee, suggested the opening run to Brighton on April 5th, the Easter Tour, and mentioned that it was hoped to organise the London-Edinburgh run. A long discussion then followed as to whether or not the club should immediately begin to organise competitions. Some were vigorously in favour of this proposal, while others pointed out the indisputable difficulties in the way of so doing. There is little doubt, however, that the opening run to Brighton will take place, and also the Easter Tour. The urgency of starting competitions soon was put forward by Mr. B. Marions, and Mr. Karlslake spoke strongly in favour of this procedure, urging that it would be desirable to hold a sixty-mile non-stop run from Broadway or Chipping Norton, or some such village, during the Easter Tour.

It was announced that the 1919 committee would consist of the following members: Messrs. Robert Head, H. G. Bell, A. Candler, A. C. Armstrong, P. G. E. James, H. Karlslake, E. Lester, B. Marions, E. M. P. Boileau, C. J. Seed, B. A. Hill, and E. Bridgman.

Mr. G. Pettytt offered a cup to the M.C.C. for a team competition between the Navy, Army, and civilian members.

Wellingborough, Rushden, and District M.C.C.

This club, which had to cease its activities, in common with others, early in the war, owing to the number of enlistments among its membership, will be again placed on a working basis in the early spring. The hon. secretary has already advertised the intention to revive the club, and has asked prospective members and old members to communicate with him at the headquarters, Queen Victoria Hotel, Rushden. It is thought full early yet to call a meeting, as there are yet to be demobilised most of the old members. It would be of great service if those interested in the club would send their names and addresses to the headquarters, so that, when a meeting is decided upon, they could be advised personally. There has been an encouraging response up to now, and a "revival meeting" at an early date may possibly be decided upon.

Newport (Mon.) and District M.C.C.

This club has not yet been restarted, owing to so many of the members being with the Forces. The hon. secretary is Mr. F. W. De La Mare, 88, Church Road, Newport.

The Auto Cycle Union.

It is impossible to make any definite announcement yet as to what official competitions will be decided upon during the present year, but such events will be promoted as will tend to provide data for the trade and the buying public, as, for example, the Tourist Trophy Race and the Six Days Trial. In regard to the former, the question of venue is not one which can be settled by the Union alone, and permission may not be granted to hold the race in the Isle of Man.

Southampton and District M.C.

The committee of the above, having considered the re-starting and reconstruction of the club, has resolved to call a public meeting of all old members and of motorists of the town and district, which will take place at the R.G.A. Drill Hall, St. Mary's Road, Southampton, on Wednesday, February 12th. The chair will be taken at 7.30 p.m. by Mr. Alfred H. Oakley, the president of the club, and it is hoped that everyone locally interested in the motor movement will make an effort to be present. It is desired to extend the usefulness of the club in the future and widen its circle of activities, and with this end in view motorists are asked to bring forward at the meeting any ideas they may have, which will receive the fullest consideration.

Communications should be addressed to the hon. secretary, H. P. Young, Lt., Hants A.S.C., M.T. (V.), Dunelm, 87, Shirley Park Road, Southampton.

Finsbury Park C. and M.C.

At the annual general meeting of this club, the following officials were re-elected: President, Sir Geo.

A. Touche; captain, Mr. C. W. Cooke; financial and general hon. secretary, Mr. J. Evans, 33, Springdale Road, Stoke Newington, N.16.

Leicester and District M.C.C.

The secretary, Mr. Harold Petty, The Old House, Cropstone, near Leicester, informs us that his club has been revived, that there was a general meeting on the 24th ult., which was well attended, and that at the next meeting it is hoped to draw up an attractive programme for 1919.

York County M.C.C.

Mr. W. E. Asquith, the hon. secretary, informs us that it is the committee's intention to reorganise the club with all possible speed. Unfortunately, many of the members are widely scattered, and it will therefore be some time before any definite programme can be arranged. At the outbreak of war, Mr. Asquith was endeavouring to bring about the amalgamation of the Leeds clubs. Doubtless, something in this direction may be decided soon. There are a number of medals awaiting claim by the winners of the 1914 Leeds-to-London Competition. The secretary's address is, 11, Moorland Street, Hyde Park, Leeds.

Club Dates.

MEETINGS.

- Feb. 7th.—The Cyclecar Club Committee, R.A.C., Pall Mall.
- Feb. 13th.—Bolton and Dis. M.C. General, Swan Hotel, Bolton.
- Feb. 14th.—Nottingham and Dis. M.C.C. Committee, Welbeck Hotel, Nottingham.
- Feb. 26th.—York and Dis. M.C.C. General, York Station Hotel.
- March 22nd.—Auto Cycle Union General, Birmingham.

Club News.—

West Grinstead and West Sussex M.C.C.

We are sorry to note that this club is to be abandoned, owing to twenty-five of the original thirty members having given up their lives in their country's service.

East Midland Centre A.C.U.

With a view to forming new clubs in the district, the hon. secretary, Mr. J. Simmonds, 10, Cranmer Street, Nottingham, will be glad to hear from motor cyclists residing in the Newark, Southwell, Mansfield, Worksop, Alfreton, Long Eaton, and Hucknall areas, or smaller places. Mr. Simmonds will be glad to forward a list of established clubs to those interested.

Sheffield and Hallamshire M.C.C.

A meeting of the Sheffield and Hallamshire Motor Cycle Club is being called immediately, and the club should be in full swing by Whitsuntide. The hon. secretary is Mr. Dan Bradbury, 3, Fulmer Road, Sheffield.

Penrith and District M.C.C.

The majority of the members now in the Services are expected to be demobilised soon, when the club will be immediately revived. In the meantime the hon. sec., Mr. S. Barron, 9, Arthur Street, Penrith, will be glad to hear from any of the old, or prospective, members. Mr. Barron has recently been invalided from the R.A.F. in consequence of wounds sustained in an air fight.

MATTERS OF THE MOMENT.

The Political Side of our Reconstruction Problems.

Import Duty on Foreign Motors for Three Years?

THE Motor Industry Branch Committee of the Engineering Trades Committee appointed by the Ministry of Munitions has expressed the opinion that the industry needs to be assisted by an import duty on foreign vehicles and parts for at least three years.

Removal of Import Embargo.

The Autocar learns on good authority that the removal or retention of the total prohibition of motor imports depends largely upon the Government's view upon the effect that such action will have on the labour market. If the sanctioning of the importation of a certain number of foreign vehicles is likely to lead to the easing of the labour market in this country, the probability is that the prohibition will be relaxed in the near future, so that the established concessionaires in Great Britain for foreign machines will be permitted to import, under licence, possibly on payment of an import duty of 33½%.

War-worn Machines.

The Motor Industry Branch Committee report referred to above advocated a scheme under which all Government surplus vehicles are first offered to their original manufacturers for repair and overhaul. "The condition of vehicles so overhauled," the report states, "would be guaranteed by the manufacturers, and this guarantee would materially increase their market value. All vehicles, whether so repaired or not, would ultimately be marketed by the motor manufacturers and their established selling organisations, acting as agents for the Government in the matter."

Legislature.

Lord Balfour of Burleigh's Committee specifically mentioned the motor industry as one of those that has been hampered by ill-advised legislation. The Motor Industry

Branch Committee maintain that all proposals with regard to taxation should be co-ordinated, so that, in the aggregate, the burden cannot become excessive. It is also suggested that the profits of such taxation shall be so applied that the users of the vehicles taxed shall benefit. Restrictive and repressive legislation and taxation cannot fail to check the large expansion of which the industry is capable, and may even jeopardise the position which it has hardly obtained in the engineering world.

Co-operation.

The Autocar suggests that upon nearly all broad principles the interests of makers and users of motor vehicles are in line, and that, given the necessary organisation, united action between motorists and motor manufacturers would be more effective than a number of smaller and independent endeavours to secure the same end. Unity of control has been the great lesson of the war, and is urgently needed in the cause of automobilism. In the Reconstruction programme, important problems directly affecting the interests of motorists and the motor industry require the immediate and serious attention of a single influential body representing the interests of motorists as a whole.

The Proposed Ministry of Ways and Communications.

The proposed Ministry of Ways and Communications, over which Sir Eric Geddes is to preside, needs very careful watching on the part of the motoring organisations. Sir Eric Geddes's interests are with the railways, and there is a danger that our roads may be allowed to share the fate of the canals if they are placed under railway control. The R.A.C. Parliamentary Committee, which has already set to work in good earnest, urges that the Road Board should be strengthened and retained as a separate body outside the Ministry of Ways and Communications.

Readers' Reports of the State of the Roads.

IN response to our paragraph in "Current Chat" of January 23rd, readers have forwarded us the particulars given below regarding the present road conditions in the districts with which they are familiar:

Leeds-Kirkstall-Horsforth-Guiseley road. There is a tram track the whole way, and the condition of the setts in some parts is appalling. An alternative route from Leeds to Otley would be *via* Woodhouse Lane and through Headingley on to the Otley Road. Extensive repairs are proceeding on this latter stretch, and the surface is quite good. From Otley to Harrogate, *via* Pool, the surface is excellent, and large stretches have already been repaired. Harrogate (Gasworks)-Blubberhouses-Bolton Bridge is, as always, in excellent condition.

The road through Guiseley, Burley, and Ilkley is good, but between Ilkley and Addingham it is poor, and improves again between Addingham and Skipton.

The Harrogate-Wetherby road is narrow, but quite good. From Leeds to York motor cyclists are advised to go by Wetherby, the road being excellent the whole way. Tadcaster is to be avoided like the plague. The direct road joining Leeds, Chapeltown, Harewood, and Harrogate is in good order.

Hollings Hill on the Guiseley to Shipley route should be avoided. The bottom stretch is terrible.

The road Apperley Bridge, Rawdon, Yeadon Moor, *via* Pool, to Harrogate is excellent throughout.

Extensive repairs are proceeding on the Otley-Arthington-Harewood stretch. In

all cases, however, Otley itself should be avoided.

The Leeds to Bradford main road, *via* Stanningley, is in very bad condition, but there is, unfortunately, no way of avoiding it.

Readers are warned of the Westerham Road from Keston Pond to Biggin Hill, also the main Sevenoaks Road between Bromley and Farnborough, the condition of which is reported as being "worse than words can describe." The roads between Cobham and Weybridge and between the main Portsmouth Road and Weybridge are in a shockingly bad condition, the worst parts being just outside Brooklands track.

We shall be glad of notification from readers of the state of the roads in their vicinity whether good, bad, or indifferent.

HENDERSON SIDECARS.

War-time Experience in Metallurgy helps to Improve Chassis Construction.

THE latest model Henderson sidecar illustrated on this page has a distinctly pleasing appearance, and one which will appeal strongly to the sporting motor cyclist especially. To obtain this result, however, nothing appears to have been sacrificed in respect of carrying capacity.

We are informed that the question of the most suitable materials for the different parts has been studied very closely, and the makers' experience during the war has made it possible for them to construct, for example, springs of far greater resiliency and toughness than is usual. Such parts as wheel spindles are made of a special alloy steel which is practically unbreakable, while those parts which cannot be enamelled are constructed of the new rustless steel, which, it is said, will not even tarnish.

The connections are by patented adjustable joints of substantial design, as will be seen on reference to the illustration.

The latest Henderson sidecar. The design is graceful, and great attention has been paid to the streamlining of the body.

The chassis is very stiff, employing only four lugs. Long C springs are fitted at the front, and a combined semi-elliptic and coil tension spring—which acts as a shock absorber—supports the body at the rear. All spring joints are bushed and work on hardened bearings. The wheel is attached to the chassis by a stub axle supported on a stiff triangulated tube assembly. The mudguard is deeply valanced, and is attached to the body, and a substantial stand is fitted. The absence of a luggage grid will be noticed, ample accommodation for spares and impedimenta being provided in the body without cramping the passenger. There is a spacious locker

at the rear, upon the rubber covered top of which are fitted a rail and strap eyes for the carrying of two spare tins of petrol.

A novel feature is the incorporating of the sidecar lamp in the cast aluminium step, a sketch of which is given. A good streamline effect has been obtained with a semi-scuttle dash and sloping curved windscreen. A spring seat is included in the equipment, and should do much to obviate fatigue on long journeys.

Three other sidecars are to be listed—viz., a touring model, a two-seater, and a "featherweight." It is hoped to commence deliveries of all models immediately.

Showing the body suspension, which is by semi-elliptic and coil springs. Note the sidecar stand.

The sidecar lamp neatly embodied in an aluminium step.

The patented adjustable sidecar connection.

A Windscreen Adjustable to any Sidecar.

WE illustrate here a useful sidecar windscreen, which Messrs. Ollard, Westcombe, and Co., Ltd., Great Charles Street, Birmingham, intend to put on the market shortly.

Unsuccessful attempts to purchase a windshield for their own use suggested the possibilities of a demand for a light, inexpensive screen that could be fitted to any sidecar by a novice. The fact that nearly every sidecar is of different width indicated that a flexible windscreen of sufficient length to remain slightly curved, on account of wind pressure, when fitted to the widest sidecar, was necessary.

The framework of the screen consists of four pieces of small-gauge spring steel 1 in. wide riveted together, the two horizontal pieces terminating in loops or eyes, through which pass the stout side pillars, which are attached to the sidecar body by means of brackets. These pillars are adjustable to any angle within 180°, and one side is so arranged that the whole can be swivelled round to enable the passenger to enter the sidecar.

The "window" consists of a sheet of xylonite bound with webbing and having leather protectors at the corners. In

addition, it is proposed to fit a side curtain at one side, as shown in the drawing.

An adjustable windscreen, to which that very desirable adjunct, a sidecurtain, can easily be fitted.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

PARAFFIN VAPORISER.

Sir,—Referring to the notes by Mr. A. G. Cocks on page 88 of your issue of January 23rd, could you induce Mr. Cocks to let your readers know the name of the vaporiser for paraffin of which he speaks so highly? Or, if it is not a commercial article, perhaps he would be good enough to give a description of it. S.C.P.

MAKERS AND PROMPT SERVICE.

Sir,—In your issue of January 2nd I notice a correspondent complains of the dilatory methods of a certain firm. May I quote my ("other side of the slate") experience when dealing with the Hendee Co.

Having come into possession of an Indian machine, I have had occasion to write this firm several letters re spares, booklets, etc. I have invariably received a reply by return, and when parts have been ordered they have arrived by first post on the day after receipt of my order. In one case, when unable to accommodate me from their usual source of supply, they removed parts required from a stock machine. In the period covered by the above I wrote twice to English houses, and in the first case it took me five days to obtain an answer, while in the second I am still without a reply.

I add the usual disclaimer and enclose my card.

Leeds.

LIEUT.

CARBURETTOR CONTROL.

Sir,—In your issue of January 2nd I notice that a correspondent has raised a question which has puzzled me for a long time, viz.: Why not fit a pedal throttle to a motor cycle carburettor? I am quite aware that a bumpy road would make it harder to manipulate than in a motor car.

To my mind, however, a pedal accelerator fitted in conjunction with the handle-bar slides would be far and away more pleasant to use than those clumsy (to say the least) and very often badly proportioned "levers" which are usually found out of one's reach "somewhere on the handle-bars."

It appears to me to be amazing that no such fitting has been placed on the market as yet.

Why is it that probably ninety-five per cent. of motor car engines are fitted with automatic carburettors, whereas, to my knowledge, not a quarter of this percentage of cycle engines are so fitted?

Is there any difficulty in turning out a small automatic carburettor which is efficient?

R. B. FAIRTHORNE, S.-LIEUT., R.N.

LUBRICATION.

Sir,—As a constant reader of your paper, I should like to reply to Mr. Wright's article on "Lubrication" in the issue of January 16th.

My mount is a 1914 Sunbeam, which as turned out by the makers was fitted with the Best and Lloyd drip feed. This feed I eventually superseded by fitting a mechanically-driven pump of the gear wheel type. It is located on the magneto timing case cover, and driven directly off the large intermediate timing wheel. I have fitted a new oil tank directly underneath the valve timing case, from which the pump draws its oil. From the pump the oil is forced up to an ordinary sight feed, which is adjusted to drip at the required speed into the engine. The pressure of the oil delivered by the pump is regulated by a release valve, so that the oil up to the sight feed is practically always at the one pressure.

As Mr. Wright remarks, "it starts and stops with the engine," and all one needs to do when encountering a hill or hilly country is to turn the drip a notch or two faster. A further improvement would be to have the drip adjustment working in conjunction with the throttle lever.

I might mention that any oil which happens to leak through the pump driving-shaft can only go through the timing case back to the oil tank below. This system has given me every satisfaction over many hundreds of miles, and I think is certainly a step towards perfection as regards motor cycles.

If any further particulars are needed, I shall be pleased to give them. S. HUGHES.

EXPLOSION PRESSURES.

Sir,—I am surprised never to read anything about the power inside the cylinder viz., the explosive mixture of petrol vapour. The power of this must vary with the quality of spirit, and there must be a difference between the power exerted by a vapour of paraffin and a vapour of petrol.

I suppose, really, we are dealing with explosives; and it occurs to me that, with all the experience gained in relation to them the last four years, it should be possible to supply an explosive in liquid form to give us, say, 6 h.p. in a $3\frac{1}{2}$ h.p. engine. With a more powerful fuel we could have lighter machines and smaller expenses and any speed.

The thoughts and experiments of your readers on this matter would be interesting. Calcium carbide generates a very powerful explosive. Has it ever been tried? Edinburgh.

JUNO.

[Acetylene has been tried in motor cycle engines. It gives too powerful an explosion, and has been the cause of accidents. There is not much difference in the explosive force of the various hydrocarbons, though there is a little. Forced induction also has the effect of increasing the power.—Ed.]

THE THREE-JET BINKS CARBURETTOR.

Sir,—In answer to Capt. Lindsay's letter in your issue of the 16th inst., I wish to mention that I have continued my tests for the "dead spot" on Binks carburettors on several engines, both motor car and motor cycle. The results arrived at were in every case the same as I mentioned in *The Motor Cycle* of January 30th.

Regarding your correspondent's idea that a "dead spot" is not so noticeable on a four-cylinder engine, this is quite erroneous, as I have proved it is much more noticeable on a four or six-cylinder engine than on a single or twin.

He will be interested to know that the engines upon which tests were carried out were a $2\frac{1}{2}$ h.p. Sunbeam, $3\frac{1}{2}$ h.p. Triumph, four-cylinder Henderson, Morgan Runabout, Straker-Squire car, 20 h.p. Vauxhall, and six-cylinder Clement-Talbot.

In every case the consumption and power of the engines were very materially increased by fitting a properly tuned Binks carburettor. In the case of the $2\frac{1}{2}$ h.p. Sunbeam, the extraordinary mileage of 170 m.p.g. was obtained on a long run.

It is therefore perfectly obvious that the fault lies not in the carburettor itself but in the incorrect jet setting, which is purely the fault of the rider.

T. D. WHEELER, Lt.,
Instructor in Internal Combustion Engines,
Khaki College, St. Anne's.

WHICH TYPE?

Sir,—First permit me to congratulate *The Motor Cycle* on the success of the "Which Type?" referendum. I have been anxiously waiting (in this dreary and rain-swept part of the globe) for the result, which, I think, ought to be the means of great improvements in the near future.

The manufacturers know now what is in the mind of the motoring fraternity, and it is up to them to materialise on it. Will they?

There was the question of "finish" I should liked to have seen brought more forward. Existing machines have too much nickel about them. Why any at all? All black is quite good, but shows up the mud too much. Let us camouflage the background for it. The Indian red is much better; but why not all khaki, similar to the Indians and H.D.'s with the Americans here, or a grey?

ONE OF THE OLD (MOTORING) GANG.

B.E.F., France.

Sir,—As a believer in the belt drive, it is interesting to read Mr. E. B. Hall's letter in your issue of the 23rd January, commending the use of a 1½ in. belt on an 8 h.p. Matchless twin. The failure of the belt in some cases in the past was not to be wondered at when a 1 in. belt was forced round a 4½ in. pulley, the lack of frictional contact causing the belt to slip, and this the rider endeavoured to remedy by increasing the tightness of the belt.

Treatment of this nature increases the casualties in the transmission, and I have seen belts worn out after covering 500 miles.

Perhaps now, after we have all settled down to post-war business, we shall see the renaissance of the belt-driven cycle car at a very moderate price. My ideal is an 8 h.p. flat twin, variable gear, belt transmission, two 1½ in. belts running over 10 in. and 18 in. diameter pulleys.

E. OWEN DAVIES.

DYNAMO LIGHTING FOR SOLO MACHINES.

Sir,—In view of the fact that the ideal solo machine specified by your readers is fitted with a dynamo lighting set, I think that the design of a suitable outfit warrants more attention that has so far been given to it. While the outfits supplied for heavy combinations are excellent, they are too large and weighty for use on a medium-weight solo machine.

I have for some time been working on the design of a set suitable for this latter purpose, and hope before long to be in a position to carry out some tests.

I am firmly of the opinion that a constant speed drive to the dynamo (such as Lt. Olechnovich described in your issue of January 9th) is a better method of voltage regulation than the usual magnetic field control for the following reasons: The normal speed of a very small generator, such as that required for a motor cycle, is about 3,000 r.p.m. If it is geared to attain this speed at a road speed of, say, 18 m.p.h., the corresponding speed at 40-50 m.p.h. would be too high

A dynamo speed governor designed by "S.C.C."

to be practical. Consequently, makers have designed their generators to give full volts at about 1,750 r.p.m., and have geared them to attain this speed at not less than 18 m.p.h. in order to keep the maximum speed within limits. This means that the generator is larger and heavier than is necessary for its output, and also that all work below 18 m.p.h. is thrown on the battery. If, however, the speed of the generator is kept constant the normal speed can be reasonably high (say, 2,500 r.p.m.) at a much lower road speed, saving the battery, thus allowing smaller cells to be used, and also reducing the size and weight of the generator.

With regard to Lt. Olechnovich's drive, I independently thought out a similar device, but it seemed to me to be too bulky for use on a motor cycle. My own arrangement is to use a shaft drive as shown diagrammatically in the sketch

which explains itself. This could be easily enclosed, and is fairly compact. Another and more reliable device would be a V belt drive with two expanding pulleys, coupled together and controlled by a governor on the driver.

My remarks on dynamo speeds and voltage control must not be taken to apply to the larger machines used on cars.

S.C.C., R.A.F.

AIR LEAKS.

Sir,—While reading "Ixion's" "Occasional Comments" in your issue of January 2nd, I was reminded of the

Induction joint mentioned by W.H. Hunter.

number of letters which have appeared in your columns re air leakage in the induction system.

An idea which I intend trying on my bicycle (an old Indian which has the disease badly) might be of some help to those similarly situated.

I purpose fitting new induction pipes, with an extension to fit inside the dome pipe and also to serve to hold an asbestos washer, which should make

a tight joint. Perhaps the sketch will make my meaning clear. If adopted for new engines, the arrangement could be something after the style given in the lower sketch. Two rings or washers could be utilised.

W. H. HUNTER.

VARIABLE IGNITION.

Sir,—Re letter in your issue of 23rd January, signed "H.H.T.," re variable ignition and F.N. engines. This alteration can be made successfully and with decided advantage. I have had experience of it, and should be pleased to take in hand the conversion of your correspondent's machine.

E. O. STAFFORD.

Sir,—In reply to the query of your correspondent "H.H.T.," in your issue of January 23rd, re altering a four-cylinder F.N. to variable ignition, I should strongly advise him not to attempt this, as it requires alterations to the front cover of the magneto, which could only be properly carried out by a very skilled workman, and, even if it were done would not produce any advantage.

The F.N. engine is set to run at maximum advance, which could not be increased even with variable ignition, as it is sufficient for the maximum speed up to which the engine will run—about 4,000 r.p.m. The only variation that could be made is to retard at low speeds, which again is quite unnecessary if the valves and carburettor are in proper order.

As a lover of the F.N., may I reiterate the advice of the makers to let the machine alone, and not to tinker with it for the sake of doing so.

The usual disclaimer.

ERIC CAUDWELL.

ADVANTAGES OF A TWO-STROKE.

Sir,—I should like to add a word of endorsement to "Elterwater's" praise of the two-stroke. I ride an Allon, two-speed, with handle-bar controlled clutch. This machine I have been riding for purposes of military duty since June, 1918, in all weathers, day in and day out. This district (Stafford), and especially the camp, has plenty of hills, but the way the little machine romps up on top is an eye-opener. My work entails constant stopping and restarting, but this does not worry me, as the machine starts easily in the coldest of weather, and with this so-called petrol. The hand-controlled clutch, Brampton front fork springing, and a front brake that works (and is not there simply to comply with the letter of the law) are all refinements found on only the best four-strokes, and I have ridden many single-cylinder machines but never one easier of control in traffic and holding the road better under slippery conditions. The machine runs at slow

speeds without four-stroking, and everything in connection with the engine is very simple. I do not say the speed on the flat is to be compared with a four-stroke, but I would back my machine on, say, side lanes in North Wales, with nasty turns and twists and ups and downs, every time. The usual disclaimer, other than a satisfied owner.

B. A. WYNNE-YORKE, CAPT.

Sir,—I purchased a 2½ h.p. Levis in April, 1916, and, with the exception of about four runs, I have had a coachbuilt sidecar attached the whole time. I am proud to say that I have never had the slightest trouble whatever. I have the Enfield gear fitted (5 to 1 high and 10 to 1 low), all-chain drive, Senspray top feed carburettor (28 jet), E.I.C. magneto, and Lodge aero racing plug. I may say this is the only make of plug on which this machine will run perfectly, as the ordinary two-stroke plugs are of no use whatever.

I have never had any trouble with starting either winter or summer. I use very thin oil at the rate of one pumpful every three miles from a Best and Lloyd drip feed lubricator. The engine receives a quarterly overall, and carbon deposit is very scarce. Four-stroking is unknown, even at walking pace. My petrol consumption is 120 m.p.g. solo and 90 m.p.g. sidecar. The average speed is 35 m.p.h. sidecar and 45 m.p.h. solo, and overheating never occurs. Nothing has been added to this engine to improve the running. I have fitted an iron guard in front of the magneto and under the engine to protect them from mud and loose stones, as the engine is very low. The little engine has never failed on any hill in Derbyshire yet, in spite of having a fully loaded sidecar. I have many times taken three passengers besides myself up the dreaded Sir William, Mam Tor, Cowdale, etc. All such gradients as these make small difference to the wonderful little Levis.

I wonder what "Ixion" thinks about this. He can say what he likes, but there is no two-stroke motor cycle of this class with the same gears that can compare with the Levis. It is simple and easy to handle, and is, in my opinion, the only lightweight that is capable of really hard work. I am just about to overall it for the coming season, and hope to take part in a few reliability trials in the Sheffield district at Easter.

I shall be very pleased to hear from anyone who can improve on this performance with any other two-stroke. I hope that someone will take the matter up and see if we cannot arrange for a good time this year in the way of reliability trials, etc.

F. W. VARNEY.

PRESSED STEEL FRAMES.

Sir,—Your remarks on the above subject are opportune, as no doubt many firms, new to motor cycle manufacture,

A pressed steel frame designed in 1906.

are considering launching out in that direction, and it remains to be seen whether any of these or even the older firms have sufficient interest in steel girder construction to attempt to substitute that method for the tubular frame.

Mr. Barnes's frame is equally fine in appearance as the tubular frame, particularly as applied to the horizontal engine, but it may not appear so neat if applied to the V type engine.

If possible, I would like to ask you to illustrate the pressed frame design which appeared in your issue of September 5th, 1906, and which had second prize in *The Motor Cycle Improvement Competition*. This machine was designed by Mr. G. Pilkington and myself, and embodies all the present-day practice of construction applied to a pressed steel frame, which, no doubt, may be of some interest to your readers.

H. SARGINSON.

LARGER TWO-STROKES.

Sir,—I should much like to see a controversy about a 500 c.c. long stroke two-stroke, air-cooled. This appeals to me intensely as an ideal no-trouble engine. The existing two-strokes, with their light frames, frail forks, tiny tyres, and very low gear, are useless for a hard-riding long-distance man. The Scott does not appeal to me, as it is water-cooled and heavy on petrol and oil.

R. R. RICHARDSON.

AIDS TO STARTING.

Sir,—“Tired Tim’s” letter was distinctly humorous, and I am inclined to sympathise with him in his picture of any manufacturer “padding off” on a motor cycle on a frosty morning with 1919 petrol; but, in mentioning Mr. Bradshaw and the A.B.C., is not “Tired Tim” somewhat off the rails?

I am under the impression the A.B.C. is to be fitted with a kick starter.

WEARY WILLIE.

[A kick-starter will be fitted as an extra, chiefly to sidecar machines.—Ed.]

BENZOLE PRICES.

Sir,—Re your benzole campaign. In an article, “The Motoring Outlook,” *The Yorkshire Post* of January 28th says: “Certain it is that the retail price now charged is 3s. per gallon; and one does not require any special knowledge of the trade to be aware that this is considerably in excess of the price at which it can reasonably be marketed.”

Benzole producers should be made aware of the fact that, if benzole is to be marketed at the same price as high-grade petrol, motorists will turn from it in disgust and choose the petrol.”

Is not 3s. per gallon *shameful*; when I know of a man, connected with a benzole-producing firm, running on benzole at 4d. per gallon now?

H. BROCKLEBANK.

PRICES.

Sir,—I wonder if you could afford me a little of your valuable space to raise a few questions that seem to me perplexing. Why will British motor cycles and sidecars cost us so much in future? Where is upwards of £150 put into a combination? How much will a similar American outfit cost us, considering it has to pay 33½% tariff? Will it cost £200? Americans pay equal wages, if not more, and raw material costs at least equal, if it does cost this figure. How is it done? If I purchase a 1919 machine, and try to sell it in 1920, how shall I stand if the promised changes take place in design? Spring frames, overhead valves, 28×3in. wheels, better silencing, and more all-round efficiency. Have not these things been with us since 1914 on American machines? So, therefore, we shall be then just exactly six years behind our cousins. Perhaps some enlightened reader can oblige me.

PERPLEXED.

Sir,—The correspondence that has passed through *The Motor Cycle* under this heading has indeed been interesting.

I have been anxiously awaiting particulars of a new twin about to be marketed by a firm of repute, makers of a well-known single-cylinder, but after perusing “The Buyers’ Guide,” given in your recent issue, I do not hold out much hope of realising my wish.

Concerning “W.’s” comments in your issue for January 23rd, suggesting that manufacturers be content with a smaller profit, even so, but the increased cost of labour and materials over pre-war days must be recognised.

In my opinion, the prohibitive extra cost as per schedule could be reduced to a satisfactory minimum, provided makers would treat with buyers direct.

SINGLE.

BOOKS FOR MOTOR CYCLISTS

HINTS AND TIPS FOR MOTOR CYCLISTS.

A valuable collection of useful “wrinkles” and items of information concerning the running, management, and repair of motor cycles.

Price 2/- net. By post, 2/3.

TRACING TROUBLES.

Motor Cycle Faults, Their Identification, and Their Remedies Fully Explained.

Price 2/- net. By post, 2/2.

Obtainable by post (remittance with order) from

ILIFFE & SONS Ltd., 20, Tudor Street, London, E.C.4
or of leading Booksellers and Railway Bookstalls.

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Magneto Conversion.

? Please inform me if a two-cylinder magneto can be used on a single-cylinder, and if so, would it require altering?—J.C.

You can convert the magneto by removing one of the contact breaker cams.

Lost in Post.

? I sent to a London firm for a motor cycle chain, enclosing cash and postage. I understand the chain was sent by post some time ago, but it has not been delivered, and cannot be found. The firm say I must be the loser, unless I can claim from the Post Office. (1.) Is this right or fair? (2.) Should not the sender claim for loss? If the money I sent the firm had been lost, surely I could not ask them to claim from the Post Office or be the losers?—W.E.A.

As you requested the chain to be sent by post, you would have no claim against the sender, unless you can prove that the sender either had not properly packed the parcel or had not properly addressed it. Of course, if you had stipulated that the parcel had to be insured, you would have been in a better position.

Misrepresentation.

? I paid £40 for a Dene motor cycle and sidecar, stated to be in splendid condition and of 1913 date. When I got it home I found the machine frame broken. I went to the makers to see if they would repair it. They told me they had refused the same job before; that it was a 1911 turnout. I at once wrote and told the seller, and demanded my money back. This he refused. I then told him I should put the case in a solicitor's hands, and he replied that he was prepared to defend the case. On the receipt he does not state it to be a 1913 machine. Will you please tell me what to do? Can I also make a case against him for the machine not being as it was advertised—in splendid condition? I still hold the paper in which it was advertised in splendid condition; and I have never been out on the machine since I bought it, as it is unrideable.—J.H.

You seem to have a good case for damages, provided you have sufficient evidence to support your claim. It would be much the best course for you to place the whole matter in the hands of a solicitor in your district.

Petrol Tank Leakage.

? Recently I found the petrol making its way out around the holes where the four screws which hold the tank to the frame are attached. Knowing it to be an awkward job, I solicit your advice as to the method you would propose to cure it.—J.W.

There are several methods of overcoming this trouble, one being to braze in studs and put the nuts on the outside; another would be to solder in thick brass nuts and red lead the screws before tightening up. We believe Messrs. the Service Co., Ltd., 292-3, High Holborn, London, W.C.1, make a substance for this job called "Coverole."

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication.

ILIFFE & SONS LTD.

Fitting a Sidecar.

? (1.) I am fitting a lightweight sidecar to a Big 4 Norton. The back axle of the sidecar is straight, one end attaching to the chain stay of the machine. Unfortunately, this stay is only just over eleven inches from the ground. Consequently, the axle slopes down from the sidecar wheel to the motor cycle. Is this in any way dangerous or detrimental? (2.) What r.p.m. do you consider best for my engine, both as regards vibration and power? (3.) Do you think a four-point attachment (the sidecar has only three) worth obtaining, in order to make such a sidecar safer with so heavy a machine?—H.W.L.

(1.) It is certainly detrimental to fit the sidecar as suggested, alike as regards tyre wear, strain, and appearance. You could doubtless obtain an adjusting piece from the makers of the sidecar, or have one made. (2.) 1,500 to 1,800 r.p.m. (3.) We do not recommend a rigid fourth attachment on light sidecar chassis with single longitudinal tube. A strap might be used with advantage as a safeguard in case of accidents.

Legal Liability.

? If a hen run into a motor cycle and die, is the cyclist liable for the cost? The owners ask for its value.—M.R.D.D.

In the absence of proved negligence, you would not be liable for damages.

Revenue Tax.

? In January, 1918, I paid tax on a B.S.A. motor cycle, which was used till the end of April. I then bought a lightweight Sparkbrook, and used this, discontinuing the use of the B.S.A. entirely. The B.S.A. has not been used since the Sparkbrook was bought, though both are still in my possession. Am I liable to tax on the two motor cycles? I am under the impression that, as the one motor cycle has not been used since the second was bought, I am not. The Revenue authorities are rather insistent on the payment of the second £1.—A.J.J.

We are afraid you will have to pay the second tax, as the first one was paid on the B.S.A., of which you gave particulars at the time. Unless, therefore, the machine was sold or destroyed, the fact of your having or "keeping" another machine renders you liable to the fresh tax.

RECOMMENDED ROUTES.

BEXLEY HEATH TO NEWBURY.—E.B.

Bexley Heath, Eltham, Nottingham, Bromley, Beckenham, Elmers End, Croydon, Mitcham, Kingston, Raynes Park, Malden, Kingston, Sunbury, Staines, Egham, Ascot, Wokingham, Reading, Theale, Newbury.

NEWPORT (MON.) TO GLASGOW.—J.G.

Newport, Usk, Monmouth, Hereford, Leominster, Ludlow, Craven Arms, Shrewsbury, Whitechurch, Warrington, Wigan, Preston, Lancaster, Kendal, Penrith, Carlisle, Gretna Green, Lockerbie, Beattock, Abington, Uddington, Lesmahagow, Hamilton, Glasgow.

LONDON TO BURTON-ON-TRENT.—J.W.R.

Finchley, Barnet, St. Albans, Redbourn, Dunstable, Fenny Stratford, Stony Stratford, Towcester, Daventry; here you leave the Coventry Road, and follow the signposts to Holyhead along Watling Street until you come to the cross road leading from Nuneaton in the south to Derby in the north, then go through Twycross and Overseal to Burton-on-Trent.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—First 12 words or less 2/-, and 2d. for every additional word. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd., and crossed** & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge, which must include the words Box 000, c/o "The Motor Cycle." Only the number will appear in the advertisement. All replies should be addressed No. 000, c/o "Motor Cycle," 20, Tudor Street, E.C.4.

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

SOUND Repairs to motor cycles, magnetos, carburettors, etc. No notching. Skilled work only. Prompt attention, reasonable charges.—The Murt, 151, Caledonian Rd., King's Cross, London. Plating and enamelling. [3286]

BURST Motor Cycle Covers Remoulded and made perfect; broken away heads remoulded; every job a success, or cash refunded; bursts from 3/6; rubber-studded retreading, 14/6; returned carriage paid quickly.—Melton Rubber Works, Melton Mowbray. [3566]

H. AND S. will make your old machine absolutely as new; overhauls a speciality; enamelling, plating, at minimum cost. If you want the maximum power out of your engine, bring it to us and we will get it for you.—H. and S., 47, South Lambeth Rd., Vauxhall, S.W.1. [3584]

GEARS, Gears, Gears.—We make any gear part for car or motor cycle. If you require quotation, send pattern parts. Do you have trouble with your gears? If so, send your box complete to us, and we can redesign the gears when making new parts.—Cromwell Eng. Co., 327, Putney Bridge Rd., S.W.15. Phone: Putney 1601. L.S.W. Ry. [2399]

ARMSTRONG and Sturmeys-Archer Gears.—All parts for every type in stock. We repair these gears promptly. Douglas gear box parts made and stocked, also parts for countershaft gears. Let us make those replacement gears you cannot obtain.—Cromwell Engineering Co., 327, Putney Bridge Rd., S.W.15. (L.S.W. Ry.) Phone: Putney 1601. [1689]

OLIVOS Motors, 120, Bollo Bridge Rd., Acton, W.3.—We are now open to undertake all classes of motor cycle repairs and overhauls. We have experts who can tune your engine for economy, speed, easy starting, and silence. Our plant and staff enable us to guarantee all our work, and there is nothing too difficult for us to do. It will pay you to give us your consideration. What Olivos promises, Olivos performs. [X2181]

ARMSTRONG and Sturmeys-Archer 3-speed Hub Gears.—F. E. Jones, Muswell Hill, has given up the trade and supply of replacements for the Armstrong and Sturmeys-Archer 3-speed motor cycle hub gear, and the County Cycle and Engineering Co., Staines Rd., Hounslow, have purchased the stock.—The County Engineering Co. hold a complete stock of these parts, and can repair these gears at once.—County Engineering Co., Hounslow. Phone: 322 Hounslow. [2602]

TENNANT Engineering Co., Pershore St., Birmingham, pre-war engineer motor repairers, now released from Government control, are again able to undertake every description of machining and repairing in connection with motors or other form of traction. Cylinders rebored, new pistons fitted; Engines rebushed, thoroughly overhauled and restored to highest efficiency; unobtainable parts duplicated; frames altered and repaired; welding by real experts; prompt delivery; all work fully guaranteed. [X2887]

MISCELLANEOUS.

X'ALL Saddles, scarcely used; guinea.—34, Rodger Rd., Roehampton, S.W.15. [3548]

CHAINS, compression taps, and scarce sundries at reasonable prices.—Crow Bros., Guildford. [9779]

Unrationed Benzole.

COMMENCING on Friday last, benzole may now be purchased for use in motor cycles, cars, etc., without a permit from the Petrol Control Department, and therefore without the payment of the tax (6d. per gallon) which had lately been levied upon it as well as on petrol. This must be regarded as an important concession, as it is another proof that the Government are alive to the urgent need of a home-produced fuel which can compete, even in a small way, with petrol. Our readers are aware that a tax of 1s. a gallon is payable on petrol (6d. is included in the price and 6d. payable in advance to the Petrol Control Department). A short time ago the advisability of placing a similar tax upon benzole was considered, but it was finally decided not to impose the 6d. which is included in the price, and now, as we have already stated, the rest of the tax is removed. This is the first real evidence of official support for a home-produced alternative fuel for motor vehicles.

It was lately rumoured that the petrol combine was endeavouring to purchase the whole output of benzole. This step should be opposed at all costs, for if it were brought about the possibility of a cheap, or even moderately cheap, fuel would disappear into the dim and distant future. It is most desirable that benzole should be under separate control and sold at a price which will give a reasonable profit to its producers. This question of price is a very vital one, and for that reason we have repeatedly urged motorists and the motoring organisations to combine and guarantee a market for benzole at a fair price, for if this incentive be lacking the supply will inevitably fall off. It was stated last week that the gas companies were petitioning the Government against the extraction of benzole from gas. The amount of benzole to be obtained in this way is quite considerable, and we understand that when incandescent burners are used there is no noticeable difference in the illumination. We

hope, therefore, that the request of the gas companies will not be granted without due consideration being given to all the points at issue.

Again, of vital importance to the supply of a home-produced motor spirit is the question of quality. The first benzole supplied in pre-war days was inferior in this respect, and contained sulphur, which had a very deleterious effect upon the engine, causing much pitting of valves and other more or less indefinite troubles; moreover, it was dirty. Later the benzole known as 90% gave very good results if it was properly used, and though the carbon deposit was rather larger than that produced by the best petrol, it had the advantage of being more easily removed. The ignition temperature of benzole being high, knocking and pre-ignition were practically absent when this fuel was used. In fact, some engines cannot be made to knock on benzole.

In 1913 and 1914 we used benzole regularly with considerable satisfaction. The power was excellent, and when the carburettor was properly adjusted the consumption was about 20% to 25% better than when petrol was used. The jet should be reduced slightly in size, and the float weighted to allow for the higher specific gravity of benzole, and during a frost it is advisable to mix a little petrol with the benzole to prevent freezing. We have not yet had an opportunity of testing post-war benzole, but we regret to say that information reaches us to the effect that it falls short of what it should be. This is much to be regretted, and if the benzole producers, at the commencement of their campaign, content themselves with anything but the best, the results are likely to prove unfortunate for home-produced fuel. Many of us know what benzole should be like, and what it doubtless will be like when the production settles down, but if new riders experience much trouble in their early experiments with benzole, the fear is that they will discard it for good and all, and utterly condemn what really can be an excellent fuel.

AN INGENIOUS REPAIR.

Rebuilding a Cylinder and Fitting a Buffer to the Spring Forks.

AT the present time, when it is difficult to procure replacements, and it is advantageous to do all repairs possible at home, the following description of the redemption of a cylinder which seemed beyond repair should be of more than usual interest.

Owing to a faulty casting the cylinder head of my 1914 T.T. Premier blew off one day, when starting up, at the first explosion, but, fortunately, no other damage was done beyond a dent in the tank.

The makers were unable to supply a new cylinder, and welding was out of the question, as part of the head was lost. It was therefore decided that a detachable head should be fitted.

The portion blown away was only the flat top of the cylinder, so that it was possible to dress off the ragged edges

(Left) The $3\frac{1}{2}$ h.p. Premier, on which the repairs and other improvements were effected. (Right) A "cruiser" sidecar the body of which was entirely constructed by its owner.

The material found most suitable for the joint was graphited compressed asbestos fibre $\frac{3}{32}$ in. thick, painted with boiled linseed oil. This jointing material was mostly squeezed out by the pressure of the bolts, which were tightened up when warm.

The engine runs quite satisfactorily with this head, but the joint requires renewal about every thousand miles. This, however, is no great drawback, as it can be quickly replaced, and, of course, the cylinder may be decarbonised at the same time.

Easy Starting Device.

I have a small petrol tank fitted on to the top tube for starting when using heavy fuels. From it a small copper tube goes down to a hole in the induction pipe, between the carburetter and the engine. The end of this tube is beaten over to form a very small jet. For starting, the main petrol tap is left shut. The air lever is shut, and the throttle very slightly opened. The tap on the auxiliary tank is then opened, and after waiting about three seconds the machine may be pushed off and will start at once. When the machine is once started the main fuel may be turned on, and the auxiliary petrol may be shut off almost immediately. This auxiliary tank was made from an ordinary carbide tin.

At the time when the water injection craze was on this tank was used for water. The water was used on steep hills, and, although it reduced the tendency to knock, it also reduced the power, giving a much duller exhaust. It was on the whole, however, a help in hill-climbing. If used on the level it somewhat reduced the speed. Its use was discontinued for fear lest it might damage the cylinder or valves.

The Hot-air Intake.

A hot air intake is fitted, but it was rather difficult to make a neat one to suit the Senspray carburetter, because the direction of the air flowing into the carburetter had to be completely reversed. The problem was solved by getting a semi-circular bend from an old horn, which fitted over the air intake on the carburetter. The other piece, from the end of this bend to the cylinder, was made from tinplate soldered up. It was secured to the cylinder by a piece of wire which passed through a loop and went round the

cylinder between the fins, where it was quite out of sight.

Fork Improvements.

The machine is fitted with Terry spring links on the front forks. They have made a great improvement in the riding qualities of the outfit; but it was found that, when riding fast on rough roads, the forks sometimes sprang back far enough at the top end to strike the steering head. They did not strike hard enough to do any damage, but the sound of the blow was such as to be annoying to one taking a sympathetic interest in his machine. To obviate this, a rubber buffer was fitted on the top spindle bearing, between the fork girders.

The sidecar body was entirely made by the owner. The floor is of $\frac{3}{4}$ in. pine-wood and the sides of $\frac{1}{2}$ in. three-ply. The space at the back of the seat has a lid over it, and forms a capacious locker. The weight of this body is no more than that of the original wicker one, and it is very strong.

Illustrating the method of securing the rubber buffer to the top fork spindle bearing.

The valance of the sidecar mudguard, which is a great improvement, is made of stout American cloth enamelled over, and secured to the mudguard with small hooks, which pass through $\frac{1}{4}$ in. holes drilled in the guard. The roll seen on top of the tank in the near side view of the machine is a mudshield made of American cloth. It is very handy and useful, for it may be fitted and removed in a couple of minutes, and can always be carried on the machine.

J. A. D. TURNER.

On another page we tell of the road conditions in various parts of the country. We shall be pleased to hear from all road users as to the state of the roads in their district for the common benefit. Generally speaking, the majority of the main roads throughout the country are in a poor state, though brave attempts at repairing are being made by one or two of the more enlightened county councils.

(Top) Showing how the new detachable head is secured to the body of the cylinder.

(Bottom) The face of the top of the cylinder after being ground to receive the head.

and get a flat face all round, just above the valve seats. The shape of this face is clearly shown in the sketch.

A Satisfactory Job.

A pattern for a new head was then made, with four lugs for holding-down bolts, and bosses for the original valve caps. This was cast and machined, with a flat face to lie on top of the cylinder. It was held down by four $\frac{3}{8}$ in. diameter hook bolts and a $\frac{1}{4}$ in. diameter stud. The hook bolts were made of spring steel, for strength, and also to allow for expansion of the cylinder. They were located in slots cut in the cooling fins, and hooked on to a steel band clamped round the plain portion, just below the lowest cooling fin.

To ensure a gastight joint the faces of the cylinder and the head were scraped, and, in addition, a very fine groove was chipped all round the cylinder face, to prevent the jointing material being blown out.

OCCASIONAL
COMMENTSBY
"IXION"

"Clean" Design.

THAT word "clean" conveys an impression that cannot be defined. Perhaps an illustration is the best method of approaching my meaning. The other day I stood among the staff of a certain factory who were busy designing their 1920 car. Before us were the chassis of the best British and the best American car in the class which the unborn 'bus is destined to adorn. The British chassis had wooden running boards, supported by numerous brackets, covered with rubber mat, secured by aluminium beading and brass screws. Various accumulator boxes, etc., stood up four square at intervals along the boards. The gaps between the boards and the frame were filled by patent leather valances, secured by brass turn-buckles. The front and rear springs, with shackles, greasers, etc., came outside the valances. The frame was inswept at the front and upswept at the stern. By contrast the American frame had straight, flat side members, set nearer together at the front. The side members were very deep, and pressed into such a shape that they acted as valances and running boards as well. The springs were inside the frame and invisible. This car was much the prettier of the two, a far better production job, and cost 40% less to buy in this country, after paying freight, insurance, and import duty. Now which of these chassis has the more pronounced affinities with motor cycles? To select a minor item, has anybody ever yet produced a handle-bar, a crank case, a gear box, or a back wheel hub unit of really "clean" design? And cannot our designs be "cleaned" up?

The Difficulty.

OF course, a motor car is a civilised being, and wears clothes: all its indecent intestines are secreted beneath the bonnet, coachwork, and floorboards, and none of its works need show except the steering connections and back axle, which are not obtrusive. By contrast the motor cycle is a naked savage from a kraal, and as long as it is air-cooled, portions at least of the machinery must remain exposed. But there is neither need nor excuse for the myriad dirt and rust-collecting crannies which still characterise the machines of all nations. Whether we consider the handle-bar with its assortment of levers and accessories—all attached by plate-clips—or the front fork head with its telephone exchange of tangled wires, or the tank top with its filler caps, petrol valves, tube recesses, tank clips, and oiling apparatus, or the crank case, or the gear box, or the rear hub, or the carrier, we find an utter absence of smooth and shapely surfaces, and a bewildering multiplicity of what Major Matson used to describe as "tiddly bits." Until these are exorcised, our machines must continue to displease the eye and absorb hours when they require cleaning.

Clothing the Naked.

I AM not at all sure that the smooth exterior is not possible. The power unit and its subsidiary fittings are the main problem: so long as the machine is condemned to carry a bristly, spiky, amorphous unit at its centre, no designer will see the point of cleaning up such comparatively simple details as the handle-bar, crank case, and chain cover. Within the last year I have seen a 200 h.p. air-cooled engine with never a fin on its cylinders, and a powerful water-cooled car without any visible radiator. After all, the cooling draught obtained by motoring along the road is contemptible. Its average velocity can hardly exceed 20 m.p.h., and it is disqualified for efficiency—where air-cooled engines are concerned—by the fact that its nature is to impinge on only *one* side of the cylinder. You can get a better draught and a stronger draught by boxing in your air-cooled engine or your water radiator completely, and using a ball bearing fan to suck the air past the fins or the honeycomb, as the case may be. If this is once successfully attempted, the motor bicycle will, so to speak, substitute a neat pair of tailor-made trousers for its present waistband of beads and wire; and, in due course, it would add a bowler hat in lieu of painting its cheeks and sticking feathers in its hair. All of which improvements are ardently to be desired.

Pardon this outburst, gentle reader. It has been thawing to-day: my front mudguard fell off eight miles away, owing to a rusted bolt; and it is "some" cold in my garage. Also, I had been to a dance, and was too lazy to change out of dress trousers: and when Mrs. Ixion saw them laid over a chair back this morning, she said "——— !!!"

Overhead Valves.

I CONFESS to very real disappointment at the obvious decision of the motor cycle trade as a whole to adhere to side valves. In the old days the overhead valve was wisely eschewed because of the risk of fracture: this danger is wholly obviated by modern steels—there are air-cooled aero engines fitted with exhaust valves nearly 2in. in diameter, which never break, although the heads are thin and light. On the technical side there is not one solitary word to be said in favour of side valves, and least of all in connection with air-cooled engines, where a symmetrical section is so invaluable as a preventive of distortion. The real problem in the application of o.h.v. to motor cycle engines is purely practical. The public demand a certain type of engine, and a motor cycle frame offers scant accommodation for the longest dimension of that engine. Overhead valves threaten to foul the middle rail of the frame with vertical engines, and elongate the already over lengthy flat twin. So we see the Rudge people scolloping out their petrol tank to clear an overhead inlet valve, and Mr. Bradshaw mounting

Occasional Comments.—

his 400 c.c. flat twin athwart the frame. Nevertheless, I cannot help feeling that overhead valves will gain ground, as their technical merits outweigh the practical difficulty. After all, there is no great objection to inclining such valves, whilst the use of volute springs shortens the length of the stem: indeed, the latter tip is freely employed to reduce the "swing" of rotary engines.

No More Broken Sidecar Frames!

THE other day I happened to call at a factory which produced many of the sidecar chassis used by the motor sections of the Machine Gun Corps. Scottish Trials have no terrors for this concern. The machine gun sidecar units scaled 11½ cwt. apiece, and practically every item in the original chassis fractured when it was set to transport this load over the roads of France and Belgium. Little by little all the weaknesses were traced out and eliminated, the last to yield being the spindle of the sidecar wheel, for which Vickers finally produced a special brand of 100 ton steel. A director asked me if I would like to try their experimental 1919 combination. We were in an upstairs shop at the time, but a dust-sheet was whipped off, I took my seat, and we curvetted down a chicken ladder and over a devastated area where works extensions were in progress. I can guarantee that this model will be worth waiting for.

Detachable Cylinder Heads.

WHILST making a round of inspection to pick up information about experimental 1919 models, I have noticed that many manufacturers are coquetting with the detachable cylinder head. It is, of course, as old as the hills, and was abandoned years ago because amateur owners experienced difficulty in remaking the joint. It would be absurd to anticipate a renewal of such troubles when thousands of owners succeed in handling the very complicated gaskets fitted to four-cylinder water-cooled car engines with loose heads. The main advantages of the detachable head are three in number, and are here given.

1. It considerably facilitates decarbonisation, especially on big twins, where a big one-piece cylinder can only be cleared if the crank case is dropped.

2. It permits the interior of the combustion chamber to be machined, which retards carbonisation, assists the cooling, and last, but

by no means least, reduces the liability of pre-ignition.

3. If side valves are retained, the construction of the valve chest is simplified. When the valve chest was cast on to the side of the cylinder, a "hot spot" was created on the cylinder wall; and the casting was complex and difficult to machine if an air passage was provided. If the valve chest is an excrescence on a loose head, it is easier to cast and to machine.

In some cases these detachable heads will be secured by dogs or clamps.

High Gear Ratios.

IN this paragraph I rashly challenge two eminent designers, whose pre-war notions, at any rate, ran counter to my own. The Rudge Co. sent us a letter (published on January 30th), in which they drew attention to the fact that their multi-gear gives ratios of 3½-6¼ to 1. For several years the ratios on Mr. F. W. Barnes's Zenith-Gradua gear were limited to a similar range. What I can only regard as a similar heresy popped up in a recent letter, criticising the inclusion of bottom ratios of 14 to 1 in four-speed gear boxes. Admittedly, the high series are suitable for (a) T.T. races; (b) high-speed solo touring; but they are found wanting for (c) the average private owner, and (d) riding in mountainous districts. Given a splendid rider who is an adept at handling and tuning a machine, such mounts are simply delightful; and, therefore, they inevitably obtain considerable prestige. Then the trouble begins. Ignorant amateurs, who are clumsy riders and hopelessly bad tuners, purchase such mounts on the strength of their sporting reputation; and the owner finds his mount an incubus in any really hilly country. Seven out of every ten riders experience extraordinary comfort when they are straddling a gear which will conquer

any hill without the aid of stunt jockeyship. The Brooklands clique will mock at ratios of 12 or 16 to 1. Let them mock. The average owner is a timid and clumsy person, and his engine is usually rather out of tune; give him a double-figure low gear, and he will bless you. Knowledge of this led Mr. Barnes to improve the Zenith from a commercial standpoint by incorporating a chain reduction, and dropping its bottom gear to 11½. For sportsmen who are also mechanics, a 3½-6¼ range is certainly ideal, but this cannot be said of every amateur rider.

Another Midland baker, Mr. S. Jones, has recognised the possibilities of the motor cycle for business purposes, and has his bread delivered by the aid of a B.S.A. tradesman's side-carrier. A load of one hundred and twenty loaves can be taken, and he finds the advantages over a horse and van are numerous, both from the point of view of convenience and of finance.

A Tabloid History of Air-cooling.

MARKED CHANGES IN MOTOR CYCLE ENGINE DESIGN IMPENDING.

By "ROAD RIDER."

THE scientific study of air-cooling was postponed until aeroplanes put a high premium on light engines. Several of the earliest petrol engines produced for road work were air-cooled, notably that of the Leon Bollée tricar. In those days engine design was so bad that even water-cooled engines were apt to run red-hot. The question of weight seemed immaterial—witness the pinions of some prehistoric motor car gear boxes, which look as if they were meant to take the first reduction off a soft water-wheel. So heavy water-cooling systems were clapped on to cars, and if motor cycle engines retained air-cooling it was supposed that 500 c.c. was its limit. As late as 1906 I possessed a $4\frac{1}{2}$ h.p. engine which made its exhaust port glow visibly at night.

Then aeroplanes brought the relation of weight to power into new prominence: and that just at a time when hot-stuff w.c. engines on sporting cars and racers had drawn attention to distortion, piston temperature, valve heats, and other problems relevant to efficient cooling. History does not relate on what lines the designer of the first Gnome engine was thinking. Let us imagine that the sequence of his reasoning was somewhat as follows:

1. The motor car type of engine is too heavy for aviation, and its torque deficient.
2. What parts of this engine can be lightened?
3. The crankshaft, crank case, and water-cooling system are some of the heaviest items.

4. If I substitute a starfish outline for a coffin plan I shall lighten the crankshaft and crank case.

5. If I make the cylinders rotate, they may keep cool without the aid of water.

So the original Gnome came into being. It kept cool enough to be usable when it was in a good humour: but at nights, when sighted from another aeroplane, it looked like a dying planet or a gear wheel heated prior to tempering. "Air-cooling no bon for big cylinders!" was the general verdict.

Milestone No. 1. Air-cooling Advances from 8 h.p. to 37 h.p. by dint of the Rotary.

The patient crowd of aviators who wrestled with the early Gnômes soon discovered that their compression became almost non-existent after a few minutes' running. Research showed that *distortion*

An air-cooled eight-cylinder V type aero engine, to which has been added a cowl to assist cooling.

The early type Gnome rotary engine mentioned by "Road Rider."

was the bugbear. What was the use of machining your piston and cylinder to an even .004in. clearance all the way round if five minutes' work swelled the section of each part to an irregular lop-sided polyhedron? One spot on the piston was trying to weld itself into unity with a swollen lump on the cylinder wall, whilst another spot, 2 or 3 mm. away, showed a clearance of .01in. Attempts to restrain this anarchical expansion under heat showed scanty success. Nothing daunted, the imperturbable Gaul discovered that, on the whole, the cylinder expanded away from the piston: so he adopted the flexible "obturator" ring—i.e., an L-shaped brass ring in the top groove, with a conventional ("packing") ring behind it.

A. Tabloid History of Air-cooling.—

which closed the gap as the cylinder bore swelled, and yet created little friction. Pilots were not as grateful as one might have expected. They came in from patrols with crank cases full of pulverised obturators: and they said things. (Incidentally, put an early Gnome cylinder alongside a typical 1914 motor cycle cylinder: and ask yourself which of the two is more calculated to distort.)

Distortion, otherwise uneven expansion, was by now recognised as the real enemy of air-cooling. Immediately a mighty Army of research workers began to grapple with it. Many of these labourers contributed their mite of fact or theory to the campaign. For example:

The leading face of a rotary engine cylinder gets more cooling than the trailing edge: ergo, this is the location for the exhaust valve.

The front side of a naked aero engine gets more draught than the reverse side: ergo, cowl the engine in suchwise as to distribute the draught.

The windward side of an engine gets more cooling: ergo, circumferential conduction round the cylinder walls will help even expansion.

Knobs of metal are the dickens: they make hot spots: à bas the fool designer who retains them.

Castings are *anathema maranatha*, unless machined: and even then the texture of the metal is not too reliable. Saw your chunk of metal across: machine it to limit gauges: and you may know where you are.

Why not run all the engines you have got, and take their temperatures at various points?

Sometimes a cylinder expands away from the piston and you lose all compression. Sometimes the piston expands into the cylinder and seizes. Research with (a) various clearances; (b) different metals might be a good stunt.

Why take the piston rings for granted? They spring outwards, and build up walls of oil resistance as they slide. One designer uses obturators (fig. 1); another employs one ring and a perforated piston (fig. 2); another prefers five rings on an undrilled piston (fig. 3). Some rings are fat, others are thin. Some pistons have waists, others have not. Ought not somebody to go into all this, or are they *all* right?

What about pre-ignition? A red-hot sparking plug or exhaust valve must heat up its neighbourhood. Do all plugs and all valve steels keep equally cool?

Some cylinders have walls as thick as a 7 lb. jam jar: others are of wafer steel, like a safety razor

blade. Some have shallow, coarse fins, like Army bread and butter. Some have deep, fine fins, like knife blades. Some are finned from head to foot: others are naked from the waist downwards. Does it really matter which?

So the great work went on. Locked sheds at experimental factories began to bristle with the weirdest contraptions. Test single-cylinder engines of 50 h.p. Huge wart-like objects swathed in aluminium quoits. Barrels bound round with Bowden brake pull-off springs. Jars sheathed in wavy copper zigzags. Brass hats and No. 8 heads pursed their lips and diffused their hush-hush conversation to intimates. At intervals a sort of thumping bellows was audible behind locked doors. Then perhaps a sound as of two giants tearing linen was heard. Or a few rafters suddenly tilted off the roof, and lumps of metal soared heavenwards in graceful

parabolas. Or the bellows continued, and the brass hat concerned presently mounted another pip. Anyhow, the nett result was:

Milestone No. 2. Air-cooling Advances to 40 h.p. per Cylinder, or 360 h.p. per Engine.

And *stationary* engines at that, gentlemen. Gone for ever, one supposes, is the rotary. No longer need a 300 h.p. engine waste 30 h.p. in overcoming its own wind resistance in still air. No longer need an engine throw out two gallons of perfectly good and very costly oil into the ungrateful atmosphere during every hour. No longer need the ungrateful mixture reach the inlet valve *via* the devious route of crankshaft, crank case, gear box, and inlet pipe. (Methinks a rotary engine's inlet valve must feel like a very fat pug hunting the ghost of a rat round Trafalgar Square.)

Well, that's that. And what about it? We shall presently see very marked changes in the design of motor cycle engines. Do not believe the merchants who tell you that considerations of cost doom us for ever to those knobby cast-iron cylinders which are to modern practice what a Saratoga trunk is to a Whitehall flapper's attaché case. Steel cylinders, machined inside and out, are little more expensive than complex castings with their high percentage of scrap. A modern efficient piston is not necessarily dearer than those prehistoric types best used for door-stoppers. The *principles* of aero engine design are directly and cheaply applicable to motor cycle engines: and a few modifications in their *application* are easily arrangeable.

Fig. 1.

Fig. 2.

Fig. 3.

BENZOLE AND THE GAS COMPANIES.

In certain districts there have been many complaints about the quality of gas, and the Board of Trade is to be asked by a number of local authorities to rescind the war-time order allowing gas companies to extract benzole from household gas. It has been maintained, however, that after extracting the benzole the difference in the calorific value of the gas is so small as to be

negligible, and that no difference in its illuminating power can be detected if incandescent burners are used. Needless to say, the authorities who desire the cancellation of the order are in the minority.

The output of benzole from this source last year was stated to have been 6,000,000 gallons, most of this being used for munitions.

Motor Cycle Design and Construction.

Notes on a Paper read before the Graduate Section of the Institution of Auto. Engineers.

A DISCUSSION upon general current motor cycle design and construction took place at the meeting of the Graduate Section of the I.A.E. in Coventry on the 4th inst., when a paper was presented by Mr. Romyns.

Many important points were introduced in the paper and in the subsequent discussion.

The general adherence to push cycle design in frame construction was criticised, together with the inefficiency of steering head designs, and the too flimsy bolts. The important feature of accessibility was taken up from many viewpoints, and American machines came in for a great deal of criticism on this score.

Whether taper rollers or adjustable bearings should be substituted for plain ball bearings in steering heads and hubs elicited the reply that there is no such thing as an adjustable roller ball bearing, as wear is not uniform, and any adjustment made is only a compromise. Also, if mud has access to bearings it makes no difference what type they are.

Shaft drive was not thought to be prohibited on account of cost, but rather that public opinion does not demand it.

Unit construction of engine and gear box was advocated, but a suggestion was made that they should be separate castings bolted together, after the manner of car units, to allow of individual removal from the frame.

The use of aluminium pistons was deprecated for ordinary use, as they are liable

to expand permanently, and the excessive clearance necessary causes piston slap. Also the excessive heat of the motor cycle engine reduces the piston to a semi-plastic condition, and also causes scoring of the cylinder walls.

The use of stainless steel was advocated for nuts and bolts, particularly in exposed positions such as on mudguards. This steel, by the way, is of very good quality, approaching that of B.N.D.

The old question of utilising the crank case as part of the frame was condemned by the author of the paper, but one or two members did not agree with this view,

principally on the grounds that it was necessary to have the metal there for oil-retaining purposes, and, as it is amply strong enough to take the stresses imposed by the frame, it would be mere waste of metal and unused weight if it were not made use of in this way.

Mudguarding was dealt with by a member who has experimented considerably in this direction, and he said that the only way entirely to obviate mud splashing by the front wheel is to bring the guards within 8 in. of the ground, and provide extensive lateral side flaps, and enclose practically the whole wheel.

The chassis layout of the 1919 G.N. cycle car, which embodies final drive by four chains from countershaft to rear axle. Note the engagement of the "reverse" by means of a sliding pinion. A description of the G.N. cycle car appeared in *The Motor Cycle* of Jan. 23.

Readers' Reports of the State of the Roads.

Particulars from South-eastern, Northern, and Midland Counties.

FURTHER details are to hand concerning the road conditions in various districts, as follow: The Westerham Road from Bromley is similar to those in the late battle zones, and accidents are of daily occurrence. The Sevenoaks Road between Bromley and Farnborough is nearly as bad.

The Folkestone coast road up to two miles out from Dover boundary is very bad, and dangerous for motor cycles. An alternative route is through West Hougham and Capel-le-Ferne. Leave Dover by Elmsvale Road; or, leaving Folkestone by Black Bull Road, which is in poor condition, go along the Alkham Valley. The Dover-Canterbury road is good, so is the Dover-Sandwich road. The road between Dover and Deal is rough in places, especially near Dover. Sandwich-Ramsgate road past Richborough Camp is very good, but closed to non-permit holders. On the Canterbury-Folkestone road via Denstone and Hawkinge, the last three miles into Folkestone are very bad indeed. Alternative route by Kingstone, Barham, and Elham, or the Canterbury-Sandgate-Hythe road (turning left after leaving Lyminge). The roads from Canterbury to Ramsgate and Margate are somewhat bumpy.

The road to Newhaven from Lewes, through the villages of Ilford, Rodmell,

and Piddinghoe, is in a terribly bad condition. Tourists are therefore advised to pass through Beddington and Heighton, which is not a main road, but better than the other.

A correspondent sends us the following particulars of the roads radiating from Doncaster:

NORTH.—The Great North Road to Darlington, Durham, Newcastle, and Edinburgh: Good condition with the exception of two or three miles after passing Wentbridge (eleven miles from Doncaster) and short lengths near Micklefield, about twenty miles from Doncaster. After passing Braham the road is good. The North Road to York (via Tadcaster): Fairly good to Tadcaster, very bad from Tadcaster to York. North Road to York (via Selby): Fairly good the whole way.

SOUTH.—The Great North Road (south of Doncaster to London): With the exception of a mile near Rossington Bridge (three miles from Doncaster), good. From Doncaster to Ollerton and Notingham, very good condition generally.

EAST.—The road to Gainsborough, Louth, etc., excellent from Bawtry onward. The road into Lincolnshire to Scunthorpe, Brigg, and Grimsby (via Hatfield and the Keadby New Bridge), fairly good straight forward from Belton via Beltoft to Althorpe; the "Tween

Rivers Road" very bad, the whole width of the road having been stoned without being rolled.

WEST.—Doncaster to Leeds (via Pontefract), fairly good to Pontefract, but bad forward. Doncaster to Leeds, Bradford, and West Riding towns (via Wakefield), fairly good to Wakefield, but bad forward throughout the whole of the manufacturing area. Motorists going beyond Leeds and Bradford are advised to travel by the Great North Road to the thirty-mile post (three miles south of Wetherby) and turn left (via Collingham, Harewood, and Arthington) for Ilkley, Skipton, Settle, Windermere, etc.

DUKES RIVERS ROADS.—The Lime Tree Avenue road deplorable, owing to timber waggons having cut it to pieces.

Ireland.

Particularly bad pieces of road in the counties of Down and Antrim are as follow:

DOWN.—Bangor to Newtownards; Newcastle to Kilkeel; Hilltown to Rathfriland; Belfast to Lisburn; Newtownards to Portaferry; Knock (Belfast) to Dundonald; and Bangor to Ballyhalbert.

ANTRIM.—Belfast to Antrim; Belfast to Carrickfergus; Kilrea to Portglenone; Whitehouse to Mossley; and Ballymena to Antrim.

Why New Models come through Slowly.

What the Manufacturer has to Contend with at the Present Time.

MOTOR cyclists are freely engaging in a double grumble just now—first at the prices which manufacturers are asking, secondly at the fact that three months have elapsed since the Armistice, and few but pressmen have as yet seen a single post-war model. High prices have already been justified in these pages, and that convincingly. Delays are equally excusable. A maker's first anxiety in these days is to keep together a staff which he has recruited with much trouble in the past. The public do not understand how delicate a matter it is to build up a first-class *personnel*. It used to be an axiom that first-class motors could only be built in Coventry: skilled mechanics now congregate in many other districts, but they are shy birds, and easily frightened away from a slack factory. So munition contracts are kept running on a reduced scale; and, if they anchor down the staff, they also hamper works reorganisation.

The Obstacles.

Then the new 'bus has to be designed and several experimental machines tried out. One manufacturer at least has got as far as sending a squad round a six days' course in the hands of some blithe boys who will do their best to break them up and discover any latent weakness. Sometimes the experimental 'bus is a lucky shot. Everything comes out dead right at the first essay, and the works staff have merely to select a prettier colour for the lining round the tank panels, or to cut the cost of an expensive bit of machining. More often something is radically wrong—cost, weight, springing, gear changing, or engine performance. Weeks pass quickly in the necessary experiments.

At last the design is finally approved, and the works begin to hum with actual preparations for manufac-

ture. The key to the position lies in the drawing office. Master drawings of every detail are made on tracing cloth, and blue prints are taken for the use of the hands. Simultaneously, the "alleys" in the shops are being replanned. Time and money are wasted if the finished machine emerges opposite the canteen entrance 500 yards away from the running shed, or if a quarter of a mile separates the erecting shop from the points at which complete engines and gear boxes appear. Useless machinery is being hustled out of the place, now that the last cartridge or tank or machine-gun has been delivered. The staff hustler is exhausting all his tact and profanity upon the railway company and the machine tool firms to get his new equipment delivered. The buyers are trying hard to get definite price quotations and preferential delivery dates from all the firms who supply raw material—steel, tubes, carburettors, magnetos, chains, enamel, and a myriad other necessities. Patterns for castings and jigs for ensuring economy and accuracy in repetition work are being frenziedly designed and made. The financial department are tearing their hair and wringing their hands. In these days of industrial unrest, shipping shortage, and Government control, few people dare say what anything will cost or when it can be obtained. Just when everything begins to run smoothly a section of the hands strike for a twenty-hour week or an extra £1 per day. No wonder that in those rare cases where the experimental 'bus was passed for production last November the first machine may not reach its lucky buyer till June. Pity the poor manufacturer. Never was any business man beset by so herculean a task. He deserves our sympathy rather than our criticism.

A motor cycle as an aid to the sport of sledging. A snapshot taken during the last downfall of snow.

1919 IMPROVED DESIGNS.

A NEW PATTERN C.A.V. MAGNETO.

WE recently inspected a new pattern C.A.V. magneto—a beautifully made and well-finished little instrument. The type illustrated is suitable for flat twin motor cycle engines. So far as its working parts are concerned, it is in no way different from other practically similar models turned out by Messrs. Vandervell and Co., Warple Way, Acton Vale, London, W., but it will be noticed that it is slightly different in shape, the magnets being of true horse-shoe form, and not rounded as in previous models. The contact breaker which the firm has adopted is simple and ingenious. As there is no fibre bush to swell and no rocking arm to stick, it can be seen at once that it possesses advantages of its own; and these two items, which give trouble under certain conditions, are dispensed with by

A new pattern C.A.V. magneto, showing how the platinum points are adjusted.

mounting the moving platinum point on an L shaped flat spring, the upper and curved end of which comes in contact with a loosely mounted roller of fibre. This in turn comes in contact with the steel segments on the contact breaker ring, which thus force back the spring, causing the points to separate.

Two tools are supplied with the magneto—one an ordinary spanner with gauge for adjusting the platinum points, and a tiny box spanner for turning the end of the screw on which the adjustable point is mounted. The method of adjustment is shown in the illustration.

K.L.G. MOTOR CYCLE PLUG DEVELOPMENTS.

A FEW months ago a reference to K.L.G. sparking plugs appeared in this journal. At that time the hand of the Censor lay heavily upon articles of this kind, but we are now able to describe the plug more fully.

As it was originally made for air-cooled rotary aeroplane engines, there can be little doubt that it will stand the temperatures encountered in a motor cycle engine.

A good idea of the construction of the plug may be gathered from the illustration, which shows three views. That on the left is an external view of the plug, which, it will be noticed, has no terminal screw, but in its place is a neat little wire clip, which is instantly detachable, and every bit as effective as the more clumsy

and more easily lost screw. The central view shows how the interior portion of the plug can be detached from the body, enabling the portion which projects inside the combustion chamber to be cleaned.

Exterior and sectional views of the K.L.G. plug.

The right hand view shows a section of the plug, and incidentally the robustness of the central electrode, which is of nickel steel and has a pure nickel end. The central electrode is wrapped in mica, and this wrapping is surrounded by numerous mica washers which are hydraulically compressed into position.

These plugs are now to be sold by the Robinhood Engineering Works, Ltd., Newlands, Putney Vale, S.W.15, at a moderate price.

Not long before fighting ceased a D.R. wrote to the Robinhood Engineering Works, and related how he had searched a derelict Boche aeroplane for souvenirs, and had chosen for himself one of the plugs. This he fitted to his motor bicycle, and thinking all the time that brother Boche, whatever other faults he might possess, was no bad judge of plugs, he thought one day to examine it more closely, and then espied the letters K.L.G.7. It was plain, therefore, that Fritz had originally taken the plug from a British machine brought down in his lines.

THE C.C. SPARKING PLUG.

MENTION has already been made in this journal of the C.C. sparking plug, but since that reference it has undergone considerable alteration. It may be remembered that the idea is to draw a minute quantity of mixture from the induction pipe, past the ends of the electrodes, and this cools them and keeps them continually clean. It also serves to prime the spot which needs it most—the place where sparking occurs.

The latest form of C.C. plug possesses an insulator in two portions, consisting of a porcelain cap, and a central portion on which are moulded a series of spirals. The upper portion of this insulator is enclosed by means of a brass casing. The lower portion of the central electrode is hollow, beneath the concave end of which is a small perforated plate on which rests a steel ball.

Projecting from the upper portion of the plug is a small union intended to be connected to the induction pipe, or, in the case of two-stroke engines, to the transfer passage. On the suction stroke a minute quantity of mixture is drawn through the tube and carried round the spirals moulded in the insulator, and, passing through a hole into the hollow portion of the electrode, issues through the spark gap, which is formed by the ball and the hollow upper electrode, at the moment when the spark occurs.

On the firing and compression strokes the ball is held against its seating.

The improved C.C. sparking plug.

A group of workers mounted on motor cycles at the K.L.G. plug factory; all these are enthusiastic motor cyclists. (In November, when an article on K.L.G. plugs appeared, this photograph was submitted to the Censor who, for some unfathomable reason, refused its publication.)

1919 Improved Designs.—

A trial of this plug on two-stroke motor cycles, resulted in great improvement in the running.

The plug is manufactured by the C.C. Sparking Plug Co., 145, Queen Victoria Street, London, E.C.4.

A SPRING SIDECAR CHASSIS DESIGN, FROM AUSTRALIA.

THE springing problems connected with overseas machines are, or should be, of interest to the British designer, not only as an indication of what is required in the Colonies, but as being of assistance in solving the suspension problems of home models.

The sidecar chassis design illustrated emanates from Australia. Perhaps the

An Australian sidecar chassis, embodying a springing device of unusual design.

most interesting feature is the system of transverse springing at the rear. The wheel cradle is hinged at the forward end and the smaller road shocks are taken up by the coil spring at the rear end. This coil spring is in turn attached to one end of the transverse semi-elliptic spring. The opposite end of the latter is hinged to the main side member, thus insulating the machine to

The chassis of the Gonther sidecar, which was referred to in last week's issue of *The Motor Cycle*. It is constructed in the main from steel pressings with welded joints, giving great strength with lightness. The main attachment is also of pressed steel. The body is intended to be sprung at the rear only, and attached to a swivelling bar at the front.

The Tan-Sad sprung pillion seat is shown with and without the addition of a foot and back rest. The petrol-can grip is formed of turnbuckles and linked metal strips.

a large extent from side stresses. Large scroll springs are provided for the further insulation of the body. The wheel has a knock-out axle to facilitate tyre repairs.

THE TAN-SAD PILLION SEAT.

WHILST we do not wish to encourage the dangerous practice of carrying a passenger on the carrier of a solo machine, it is obvious that there is little objection to the carrying of a third person on a properly-designed carrier seat of a powerful sidecar combination; and it is principally with this object in view that the Tan-Sad Co., 46, Weaman Street, Birmingham, are developing their series of spring carrier seats.

The general design has been altered to give a better cushioning effect, three coil springs being used at front and back—six in all. The two centre springs can be removed, when required for lightweight use only. A link action in the frame gives a parallel movement as the springs are compressed.

Upholstery has been avoided, and a plain metal seat provided, curved to a comfortable shape, upon which a cushion may be strapped if desired. Wooden handles may be added as further security for the rider, and for a solo machine a jockey type of stirrup gives support for the passenger's feet. When in use with a sidecar, with the passenger sitting sideways, a footrest and backrest can be fitted.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication.

— ILIFFE & SONS LTD.

A can of petrol may be firmly fixed on the seat, when not occupied by a passenger, by the use of a patent grip.

The fixing of this pillion seat to the carrier of the motor cycle has not been altered, the same principle of right and left-threaded rods operating clamps in the underframe being employed.

The intention of the firm is not to market a particular series of models, but to leave it to the purchaser's wishes as to how, and with what, he will fit up the seat. Prices are not definitely settled yet, but will be quite reasonable. Production is being commenced at once, and delivery should be possible in a few weeks' time.

A PLUG FROM THE U.S.A.

WE have received particulars of a plug with separable electrodes which, although it has been on the American market some time, is not so well-known over here. The insulation is composed of layers of mica wrapped round the central electrode, the whole being compressed into a hardened steel shell, which is screwed into the main body of the plug, the joint being rendered gastight by the interposition of a copper-asbestos washer. The plug body is of case-hardened steel, with the washer permanently attached. The electrode is bent in the form of a semicircle round the central "point," and fixed at both ends. The porcelain collar merely serves to protect the mica insulation. It is hoped to put these plugs on the English market at an early date, at a price of about 4s. 6d. The British distributor is Mr. Louis N. Cooper, 117, East Road, City Road, London, N.

The Benton (U.S.A.) plug.

SPRING OR RIGID FRAMES?

Final Article on the Various Points of Specification as voted for by Readers of "The Motor Cycle" in the Recent "Which Type" Referendum.

IN the issue for January 23rd we gave the proportionate voting of readers on types and systems of transmissions, while previous articles have dealt with engine types and sizes and their equipment.

The voting on the various types of gears and clutches omitted from the article in that issue was as follows:

TYPES OF GEARS.

	Solo.	Sidecar.
Epicyclic gears	6% ..	5.8%
Sliding gear	37.7% ..	35.8%
Dog clutch	51.2% ..	51.9%
Expanding ring	5.1% ..	6.5%

TYPES OF CLUTCH.

{Dry plate	69.3% ..	67.6%}
{Wet plate	30.7% ..	32.4%}
{Single	35.1% ..	18.3%}
{Multi	64.9% ..	81.7%}
Cork inset	22.6% ..	21.9%

CLUTCH CONTROL.

Hand	30.5% ..	23.5%
Foot	4.2% ..	10.7%
Hand and foot	65.3% ..	65.8%

The following figures give the results of the voting on other details of specification. The first of these is the question of spring frames, from the figures regarding which it will be seen that *The Motor Cycle* campaign in favour of spring frames has borne good fruit, and that the demand for this type of frame from both solo and sidecar class of rider is most insistent.

	Solo.	Sidecar.
Rigid frames	21.1% ..	15.2%
Spring frames	78.9% ..	84.8%

It is interesting to note that those who did not favour spring frames specified some means of insulating the rider from road shock, such as the Edmund and Bat semi-spring frames or a spring saddle-pillar. The voting on the three systems affecting riding comfort only, as distinct from complete springing of the machine, was as follows:

	Solo.	Sidecar.
Conventional saddle	77.2% ..	70.7%
Sprung saddle-pillar	15.5% ..	18.5%
Semi-spring frame	7.3% ..	10.8%

The popularity of the diamond frame in both classes is very clear, but from the voting one gathers that this should be of the duplex type.

DIAMOND OR OPEN DESIGN.

	Solo.	Sidecar.
Diamond	88.4% ..	85.7%
Open	11.6% ..	14.3%

OTHER DETAILS OF DESIGN.

Loop design	25.1% ..	27.7%
Girder design	32.5% ..	27.6%
Duplex design	42.4% ..	44.7%

Handle-bars.

Considering the known popularity of the semi-T.T. handle-bar, it is not surprising that in both classes this type has a distinct lead, while the D.R. type comes second in the solo group.

	Solo.	Sidecar.
Upturned	13.6% ..	30.9%
Flat	8.3% ..	19.7%
Dropped	2.3% ..	2.2%
Semi-T.T.	58.6% ..	39.7%
D.R.	17.2% ..	7.5%

Present-day brakework has been the subject of criticism many times, and on the voting on this point makers no doubt will have material for thought, as the most conventional type of front brake is the one scoring the lowest number.

FRONT BRAKES.

	Solo.	Sidecar.
In V rim	49.6% ..	43.9%
Conventional shoes on rim ..	13.4% ..	8.3%
Expanding	21.7% ..	39.6%
Contracting	15.3% ..	8.2%

REAR BRAKES.

Inside V rim	28.8% ..	14.8%
Outside of V of rim (conventional)	17.1% ..	11.9%
Expanding	36.7% ..	57.4%
Contracting	17.4% ..	15.9%

The demand for quickly detachable wheels is most emphatic, no less than 91.6% voting for them in the solo class and 96.8% in the sidecar group.

On the question of lighting, the majority favour the dynamo lighting set, the conventional gas generator coming second. The voting was as follows:

	Solo.	Sidecar.
Dynamo	65.9% ..	67.6%
*Battery	6.5% ..	7.7%
Generator	20.0% ..	14.5%
Gas cylinder	7.6% ..	10.2%

This concludes the results of the voting, and we think both trade and rider will have learnt something of value from them. Whether we shall see machines on the lines set forth by our readers staged at the next Olympia Show remains to be seen. We know that quite a number of designers have followed the plebiscite very closely, and, unable to wait for the results to appear in *The Motor Cycle*, have telephoned us concerning various points in order that they may give them consideration for inclusion in the new models they are now designing.

In conclusion, we thank the thousands of readers who have sent us their ideal specifications. In subsequent issues we hope to deal with the hundreds of suggestions for the improvement of motor cycles, which formed the second part of our competition.

*Of these a few specified the F.R.S. system of lighting from the magneto, with a dry battery in reserve for use when the engine is not running.

TIME TO LIGHT LAMPS

GREENWICH TIME.

Feb. 13th	5.38	p.m.
" 15th	5.42	"
" 17th	5.45	"
" 19th	5.49	"

Prices.

Despite the high prices of 1919 motor cycles, manufacturers report a "brisk" demand.

Handle-bar Muffs.

This is the time of the year when handle-bar muffs add to the comfort of riding, yet very few are seen in use.

Police Traps.

We are informed that there is a trap working outside the Hotel Cecil, in the Strand, London, where attention is paid more especially to number plates, to see if they are defaced in the daytime or not illuminated at night.

We also hear that a further trap is working in Sloane Square.

Munitions and Motor Cycles.

The combination of three large all-British engineering firms to produce the Angus-Sanderson car sets an example to the motor trade. It is a policy discussed throughout the war to meet foreign competition. Only by greatly increased outputs and specialisation can the price of a car or motor cycle be reduced very considerably, and it will be interesting to see if the policy is adopted by a fusion of motor cycle manufacturers.

Drivers for Women's Legion.

Motor drivers are still needed in connection with the Women's Legion. An enormous number of women have received motor driving training at the various schools, and it is not too late for them to apply this knowledge to useful account. Particulars as to how to join the Army Service Corps may be obtained from the Commandant, Women's Legion Motor Drivers, 15, Pall Mall East, S.W.

The Industrial Reconstruction Council.

The fourth lecture of the series arranged by the Industrial Reconstruction Council will be held in the Saddlers' Hall, Cheapside, E.C.2, on Wednesday, February 19th. The chair will be taken at 4.30 by the Right Hon. Lord Leverhulme, and a lecture on "The Responsibility of Trade Unions in Relation to Industry" will be delivered by the Right Hon. J. R. Clynes, M.P. Applications for tickets should be made to the Secretary, I.R.C., 2 and 4, Tudor Street, E.C.4.

SPECIAL FEATURES

TABLOID HISTORY OF AIR-COOLING.

SPRING OR RIGID FRAMES?

WHY NEW MODELS COME THROUGH SLOWLY.

Gloves.

Gloves that fit tightly upon the hands are as bad as no gloves at all, at this time of the year.

How they "Collect" the Motor Cycle Tax in France.

The French Chancellor of the Exchequer has just issued an illustration of the official plate for 1920, which must be carried on all French motor cycles, either on the steering head or the diagonal down tube of the frame. It is depicted in the accompanying reproduction, which is the full size of the plate, measuring 2½ in. wide x 1½ in. deep.

Sidecars and solo motor cycles provided with more than one seat will have to carry two of these plates, the second of which must be fixed above, below, or alongside the first. This plate is the official receipt for the annual tax, and there is therefore no doubt about it having been paid. A plateless machine is an advertisement of non-payment.

Canadian Roads.

The Government of Quebec has spent approximately £3,000,000 on roads in five years. In 1907 the Quebec Government and municipalities systematically maintained 1,000 miles of highways. This total had jumped to 18,000 miles in 1916.

The British Middleweight Machine.

After the experience of U.S. despatch riders with British solo machines, there is a tendency in America for consideration of the "middleweight" type of machine on the lines of the British 4 h.p. single. A writer in the American *Motor Cycle and Bicycle Illustrated* states: "British middleweights, are splendid machines but expensive."

The Scottish Demand.

Like most farmers, those in Scotland have done well during the war, and practically every farmer one meets in the Lowlands, states his intention of purchasing a car when conditions relax somewhat.

"They will all buy Fords," sighed a garage owner to our representative.

"What about sidecar outfits and cycle cars?" enquired the latter.

The garage man shook his head. "They know Fords," he said, "but they regard everything else as complicated."

Yet there is nothing simpler than the modern motor cycle, if only this fact were realised.

In view of the high price of second-hand motors, it is refreshing to hear of anything selling cheaply. A reader of *The Motor Cycle* bought the Morgan illustrated for £82 10s. It is a 1914 model, with J.A.P. water-cooled engine, disc wheels, electric lamps, accumulator tools, etc., and in excellent condition. He has had offers for it of £110 and £120.

Ivy Two-stroke.

Ivy de Luxe two-strokes for 1919 range in price from £42 to £53, the former being a single gear model and the latter the I.O.M. T.T. with two-speed gear.

The British Motor League.

A new motoring organisation has made its bow to the public—The British Motor League. The new league intends to offer the same kind of legal assistance to its members as do other organisations—but it is to be more “democratic.”

Pressed Steel Frames.

The number of pressed steel frames and the interest taken in the subject is rather noticeable just at present. “Mechanicus,” contributor of the article “Sidecar Design,” May 23rd, 1918, suggesting a pressed steel frame for a four-cylinder sidecar unit, writes us that he is particularly gratified to notice the advances that are being made in the direction of pressed steel frames, and hopes to see his suggestion for the sidecar combination adopted very shortly by a firm of motor cycle manufacturers.

The Cyclecar Club.

A special general meeting of the Cyclecar Club will be held towards the end of March, and there will be several interesting items on the agenda. It is proposed that the club, which will be re-started as from April 1st, will be known as the Junior Car Club, that its light car members will be affiliated to the Royal Automobile Club, and its cycle car members (owners of three-wheeled vehicles) will be affiliated to the Auto Cycle Union. A list of events, runs, and other fixtures will be arranged for 1919, and a design for a new badge is to be prepared.

INDEPENDENT OF TUBES AND BUSES.

There was quite a noticeable increase of motor cycles and sidecars in the City during the strike last week, and the utility of the motor cycle was exemplified in no uncertain manner judging by this loaded sidecar.

THE DISPOSAL OF ARMY MOTOR CYCLES.

At the time of going to press very little information can be added to our previous statements regarding the disposal of War Office motor cycles. The Surplus Government Property Disposal Board appears to be organising, and has appointed seventeen controllers to deal with the different classes of property. Lt.-Col. C. V. Holbrook is the controller in charge of the Mechanical Transport section. In accordance with arrangements made with the various Government Departments concerned, no surplus property will in future be disposed of except through, or by arrangement with, the Disposal Board. A special section is being set up to deal with sales to neutral countries.

The Velocette.

The prices of the Velocette given in our Buyers' Guide have been withdrawn.

Price Fixing.

Concerted price fixing by any industry is regarded as a restraint of free competition in the U.S.A., and therefore illegal.

The Latest Service Journal.

The Albatross is the title of the newest Service newspaper. As its name denotes, it is an Air Force production, and its home is Blandford Camp, the principal R.A.F. depot. It is edited, printed, and published at that delightful spot so endeared to both officers and men of the R.A.F., and the first number is a most promising one.

Morgan Prices.

1919 Morgans have been raised in price slightly above the figures shown in our recent Buyers' Guide. The sporting model is now £145; the G.P. £150; the De Luxe a.c. £150, w.c. £160.

The A.C.U. Six Days' Trial.

Although nothing has yet been officially announced regarding the A.C.U. Six Days' Trial, it may be taken as practically certain that this will be held next August, and that the course will be in the Wye Valley district. No doubt a capital series of day trials can be arranged radiating from, say, Chepstow, and a great deal of new ground to A.C.U. competitors could be included. Thirteen years ago the Six Days took in a portion of South Wales.

United Action.

A conference of representatives of all motoring organisations has been called for to-morrow (Friday) by the Motor Legislation Committee, 83, Pall Mall, of which Mr. Joynson-Hicks, M.P., is chairman, to consider the best means of removing the war restrictions on motor vehicles, the restoration of roads and bridges, and the provision of a plentiful supply of fuel at reasonable rates.

The Committee is opposed to the placing of the roads and railways under the proposed Ministry of Ways and Communications, and advocates the reconstruction and strengthening of the Road Board.

This united action has been strongly advocated by this journal and *The Autocar*.

French Tariff.

The French Government is still keeping the 70% *ad valorem* tax against the British motor trade, and French manufacturers say they need this protection for at least another twelve months.

Import Duty.

The authorities consider that by protecting the British motor industry by means of a tariff against foreign imports, skilled mechanics in the R.A.F. and R.A.S.C. will be given a better chance of finding employment.

CLUB NEWS.

Nottingham and District M.C.C.

The meeting of this club arranged for February 14th, and notified in last week's issue as a committee meeting, is to be an extraordinary general meeting, to which all local motor cyclists are invited.

South Birmingham M.C.C.

A preliminary meeting of this club was held at headquarters, "The Mermaid Hotel," Stratford Road, Birmingham, on Monday evening, February 3rd.

It was decided to call a general meeting of the club on Thursday, February 27th, at 7.30 p.m., and all district motor cyclists are invited to attend.

Birmingham M.C.C.

At a committee meeting of the B.M.C.C. it was decided to hold the opening run on April 5th, to Stratford or Evesham. All past and present members, with their motor cycling friends, are invited to participate in this social run.

Strictly speaking, this will not be a competitive event, but it is intended to award prizes and souvenirs to those taking part. Full particulars will be announced later.

The competition programme for 1919 will be a most attractive one, and motor cyclists, both experts and novices, will be well catered for. All those who are desirous of becoming members should communicate with the hon. sec., Mr. W. H. Egginton, 76, Earlsbury Gardens, Birchfields, Birmingham.

Essex M.C.

It has been decided to hold the annual meeting of the above club in London on March 4th; the actual venue will be announced later.

An active and attractive programme is being arranged for this year, and will include events which have been so popular in past years. The club is financially in a very strong position, having about £200 in hand.

The hon. secretary, Mr. D. S. Kapadia, Algers Road, Loughton, Essex, is anxious to hear from old members still in the Forces, and also from prospective members.

The attention of members of the club using the district of Woodford, Snarebrook, etc., is called to the very active police supervision that is now going on in this district, motor cyclists being stopped in several places.

The Motor Cycling Club.

It has been definitely decided to hold the annual opening run to Brighton, which has not been held since 1915. It is expected that this popular gathering will be well attended. Further details will be published in due course.

It has also been decided to hold the usual M.C.C. Easter tour, concerning which there will be a further announcement.

It has been decided to hold, in the middle of March, a smoking concert for members of the M.C.C. and their friends. Newly elected members are reminded that they are liable for the entry fee of 5s. and subscription, which will be demanded when competitions begin, not exceeding one guinea. Hon. sec., Mr. Southcombe May, 15, Endsleigh Gardens, London, N.W.1.

Club Dates.

MEETINGS.

Feb. 13th.—Bolton and District M.C. General, Swan Hotel, Bolton.

Feb. 14th.—Nottingham and District M.C.C. Committee, Welbeck Hotel, Nottingham.

Feb. 21st.—Sutton Coldfield A.C. Annual.

Feb. 26th.—York and District M.C.C. General, York Station Hotel.

Feb. 27th.—South Birmingham M.C.C. General.

March 4th.—Essex M.C. Annual.

March 22nd.—Auto Cycle Union, General, Birmingham.

EVENTS.

April 5th.—Birmingham M.C.C. Opening Run to Stratford or Evesham.

April 5th.—M.C.C. Opening Run to Brighton.

April 21st.—M.C.C. Easter Tour.

April 21st.—Dublin M.C.C., Dunlop Cup Reliability Trial.

June 9th.—Dublin M.C.C., Whit-Monday Trial.

June (end of).—Dublin M.C.C., Twenty-four Hours Reliability Trial.

August 2nd and 4th.—Dublin M.C.C., Two Days Reliability Trial.

A COMBINED VARIABLE COMPRESSION RELEASE DEVICE.

A DEVICE, which we illustrate, has been patented by A. S. Baylis, 2, Lowther Street, Coventry, the object of which is to combine the functions of the exhaust valve lifter, a decompressor, petrol injector, and compression tap. It is intended to be operated by an

A patented device embodying in one instrument a release valve, decompressor, petrol injector, and compression tap.

adjustable lever on the handle-bars. The main feature of the construction appears to be a valve which may be gradually opened, releasing some of the gas under compression. The outlet from the body of this valve also embodies a double-seated valve of the mushroom type, which seats automatically on the explosion stroke and on the induction stroke. A priming device is also incorporated, operated by a milled nut, and connected to the petrol tank by a pipe.

A POINT FOR BENZOLE USERS.

THE fact that benzole can now be obtained without the formalities of a licence will doubtless impel many to times in these pages, when benzole is used in a car-take advantage of it. As has been pointed out many burreter adapted for petrol it is necessary to make provision for an increased air supply. We repeat this information, as we have recently heard many complaints from benzole users as regards the tendency of this fuel to gum up the valves and dirty the engine internally—a state of affairs which is generally due to too rich a mixture. If the carburetter is not already fitted with an adjustable air supply, it is certainly worth while to get one, simply drilling a hole in the induction pipe and arranging a clip cover. A good-sized oil cup, threaded into the induction pipe, is quite satisfactory, the extra air being allowed to enter or shut off, simply by opening or closing the lid of the cup. It should be placed downwards, so that grit cannot collect in the bowl of the cup. This is a simpler arrangement than changing the jet each time the fuel is changed. If benzole be employed and the maximum amount of air given, truly astounding m.p.g. can often be obtained.

THE CONNAUGHT PEACE MODEL.

New Model of a Pioneer Two-stroke Lightweight.

The peace model Connaught $2\frac{1}{2}$ h.p. two-stroke.

NEW models of the Connaught are always of particular interest, if only on account of its position as one of the two pioneer simple two-strokes which popularised this useful type of machine. After four years of war, one naturally expects alterations from a firm manufacturing its own engine, but although the Bordesley Engineering Co. has been practically exclusively engaged upon "munitions" during the war, the principals have found time to experiment. The results of these experiments have not brought forth any discoveries necessi-

tating alterations to the engine, consequently the peace model Connaught follows the pre-war models closely, with the addition of minor refinements.

The engine has a bore and stroke of 73 mm. and 70 mm. respectively, the capacity being 293 c.c., and, as in the pre-war model, the cylinder is offset, which, it is claimed, permits of a more effective scavenging by reason of the slow movement of the piston at the points of exhaust and intake. The exhaust and inlet ports are superimposed, so that the mixture passes into a chamber in the

manifold, which is separated from the exhaust chamber by a thin partition of steel. By this means the cold gas takes up some of the heat of the exhaust, cooling the later, and becoming more thoroughly vaporised. This feature is patented, and is used in one or two other leading makes under licence from the Connaught firm.

It may be remembered that it was the Bordesley Engineering Co. which introduced the petrol system of lubrication into this country, and, while it was much ridiculed at the time of its introduction, it has been found fully efficient for two-stroke engines, not only by the Connaught concern, but also by many others. The war-time experiments of the makers of this lightweight have been with lubrication, and it is interesting to note that they still retain the system, and have every confidence that it is the best method of introducing lubricant into the engine.

One of the new features of the machine is the tank, which is most pleasing to the eye. The edges have broad bevels, and with the aluminium and red panels give the machine a very distinctive appearance.

The machine is fitted with 26×2 in. tyres, and weighs 125 lb., with single gear, all-belt drive, the price being £42. With a countershaft two-speed gear and clutch, the price is £53, and without clutch £49 15s.

A miniature model with 24×2 in. tyres is also catalogued, a single gear machine at £34 and a two-speed at £42 15s.

THE SCOTT SOCIABLE.

A New Company formed to Market Mr. Alfred Scott's Three-wheeler.

AT the time we introduced the Scott Sociable to the motoring world in 1916, we characterised it as a most praiseworthy attempt to solve the problem of weatherproofing the most economical form of two-seater. Owing to the war, the idea of manufacturing it in quantities had to be postponed. We are now in a position to announce that new and extensive works have been acquired in the Bradford district for the manufacture of the Scott Sociable in big quantities. The Scott Autocar Co., Ltd.—an entirely new company, under the management of Mr. C. Tunstall, who formerly held a similar position with the Scott Engineering Co.—will market the runabout, which, incidentally, is to retain the original title of Scott Sociable, the designation given it by the Editor of *The Motor Cycle*.

The specification of the Sociable which we described and illustrated in detail on July 27th, 1916, and January 4th, 1917, is as follows: Vertical two-stroke water-cooled engine, 76.2×63.5 mm. bore and stroke—578 c.c. capacity, clutch situated in flywheel, three-speed gear, shaft drive, triangulated frame sprung fore and aft, detachable and interchangeable disc wheels.

The car literally bristled with ingenious features, as do most Scott productions, and we feel sure that our readers will hail the announcement with joy, since it

brings nearer to successful accomplishment the two-seater weatherproof passen-

ger vehicle at a price approaching the £100 mark.

The Scott Sociable, produced in 1916, with Mr. Alfred A. Scott, A.M.I.A.E., the designer, at the wheel.

A Water-cooled Sidecar on the Scottish Hills.

Conditions Affecting its Efficiency.

A GREAT deal has been said in favour of water-cooled engines, more especially for sidecar use, and the Scott motor cycle stands out as an example of the suitability of the system for solo use. My own experience of water-cooling is that it is eminently successful in a moderately undulating country. It is, however, apt to be a nuisance when one's riding is done over really mountainous roads, such as one encounters in Scotland, where eight or nine mile rises are commonly met with in passing from one valley to another. Water-cooling is entirely dependent upon a current of air for cool running. Recently my journey lay over the mountain tops in the teeth of such a gale that we had nine miles of low gear work ere we gained the height of land, yet there was no suggestion of boiling, and the engine demanded a minimum of oil. On the return journey we had the gale behind us, and, though we resorted to low gear only for two miles or so, the water in the radiator was all but boiled away ere we shut off for the descent.

Disadvantages of the System.

Repeatedly this has been my experience with water-cooled engines. Travelling against the wind all goes well, but with a following wind the least excess of low gear work brings the water to boiling point. This is a great nuisance, since one is compelled to stop in order to fill up, quite apart from the mess that is created by the radiator overflowing.

The pith of all this is, then, that a water-cooled engine is more dependent on the wind for retaining its proper temperature than is an air-cooled engine.

Of course, there are two sides to the question. It may be argued that, whereas the water-cooled simply boils, thereby giving visible warning, but at the same time retaining its full power, the air-cooled overheats till finally it peters out, which is bad for the engine and more annoying for the rider. But does a modern air-cooled engine overheat to that extent under the same conditions? My opinion is that it does not. It may attain a temperature far and away above boiling point, but boiling point is an unnecessarily low temperature; therefore all the trouble that is caused by the radiator boiling over is the result of quite unnecessarily attempting to keep the engine at a lower temperature than good results demand.

Of course, if one is using a 500 c.c. engine for hauling a sidecar over these mountain roads water-cooling is thoroughly worth while and calculated to prevent many a konk, but taking a modern sidecar outfit of, say, 8 h.p., it is very seldom one experiences overheating provided the engine is properly tuned. Curiously enough, moreover, the conditions which cause an air-cooled engine to overheat are often the reverse of those which cause a water-cooled to boil.

I have had an air-cooled overheat when slogging away for miles on middle gear against a wind, whereas a water-cooled seldom boils under these conditions; similarly, it is very seldom I have had an air-cooled overheat with a following wind, as often happens in the case of a water-cooled engine.

The Future of Water-cooling.

Interesting though the water-cooled motor cycle engine is, there is every probability of the system dying out entirely except in such engines as the Scott, which is a type by itself. Vast strides have been made in air cooling, with the result that the more elaborate system becomes superfluous, and the general tendency will be with internal combustion engines of every type to adopt the simpler method. Water-cooling is a complication, and for the motor cycle a very significant one. The additional weight, though not so great as one would imagine, is a consideration, and the whole question revolves round the point—is it necessary? It would seem that the only factor to warrant the water-cooled motor cycle engine is the inefficiency of air-cooling, and as it cannot be claimed that the air-cooled engine is inefficient, since it is calculated to become in the future infinitely more efficient than in the past, there would seem but a poor prospect for the water-cooled.

Over and above all this, however, the water-cooled engine is not to be lightly discarded. It has been retained by many of the world's leading engineers in aero practice, where the question of weight, etc., is all important, solely on account of its superior durability and reliability, its economy in lubrication and sparking plugs. But aero engines are not up against the difficulty that motor cycle engines are up against. The former are not so much limited in the area of the radiator used, and are always assured of a sufficient cooling draught. In motor cycle practice we are compelled to use a radiator of small area, and we cannot afford to carry a large volume of water.

CHINOOK.

THE MOTOR CYCLE INDUSTRY.

There is scarcely a motor cycle factory in this country which has not been extended during the war. In some cases large manufacturers have doubled their output facilities, while a few of the firms which in pre-war days were regarded as small concerns are now in a position about equal to that of better known makers in 1914. At least one Midland firm has so expanded that facilities now exist for an output of 200 machines per week, whereas before the war their average output was less than a dozen motor cycles.

LETTERS to the EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

THE THREE-JET BINKS CARBURETTER.

Sir,—I have followed with interest the correspondence on the Binks carburetter, and having used one for some time, perhaps my experience may be of interest to others. The carburetter is fitted to a $\frac{1}{4}$ h.p. Precision engine (single cylinder) in a sidecar combination. Total weight without driver or passenger is 4 cwt. Jets in use are 000, 4, and 10.

(1.) *Starting*.—With pilot jet open, extra air closed, and carburetter flooded, the engine will start in frosty weather at first kick on 95% benzole. Present day petrol requires an injection in cylinder as well.

(2.) *Jet Sizes to give Single Lever Control*.—Jets 000, 4, and 10 give approximately correct mixture in temperatures from 45° to 60° F. until the engine is warm, when extra air has to be given to get correct mixture. If 0000 and correspondingly smaller jets are used the mixture is about right when the engine is hot, but starting is difficult, and the mixture is too weak unless the engine is warmed up for several minutes before moving off. The mixture gets too rich and causes petrol choke when the pilot jet is nearly shut off, which necessitates adjustment of extra air lever for slow running.

(3.) *Dead Spot*.—With 000, 4, and 9 jets the dead spot occurs when opening on to the main jet unless the throttle is opened up very slowly. Different settings of air slide over the bottom air holes seem to have little effect.

I find it best to use a 10 jet for the main, as this practically cures the dead spot, but necessitates using much more extra air with the main jet in action. I find this an advantage, as when hill-climbing with full throttle one can shut off a little air and enrich the mixture.

It is useless with this carburetter to slam the throttle open, as the engine air chokes at once and fails.

(4.) *Consumption*.—I get 70 to 75 m.p.g. on straight runs with passenger. The best I could do with another carburetter on the same engine was 55 m.p.g.

(5.) *General*.—The engine is much more responsive to control than with the previous carburetter. It will tick over in free on the pilot jet at 250 to 300 r.p.m. Acceleration is better, and power on full throttle is much greater.

I think the Binks is the nearest approach to an automatic carburetter that has yet been brought out, but it fails in one respect, i.e., compensation for temperature variation, and unless this is overcome I fail to see how any carburetter can be called "automatic." I should not like to use the Binks without the extra air lever fitted.

Arriving at the correct jet sizes for any particular engine is a matter of much experiment, and I think many users have never got the best results because they have not spent time on this.

Usual disclaimer.

A. SHARVELL CULLWICK.

Sir,—There is a self-complacency about Lt. Wheeler's letter of February 6th which is generally found only in the incubations of the very young.

I believe that Mr. Binks claims to have sold upwards of 20,000 carburetters. Lt. Wheeler has apparently tested something less than ten, and upon the strength of that he is apparently prepared to assert that none of the remaining 19,990 has a dead spot, and this in spite of Mr. Binks's own explanation (see letter published on September 12th, 1918) of the causes which occasionally lead to a dead spot.

Personally, I regard Capt. Lindsay's letter a better testimonial to the Binks carburetter than Lt. Wheeler's; for the former has had a large experience of the carburetter, and

must have found some considerable advantages which outweigh the single disadvantage of the dead spot—in fact, he says so in his article—while the latter's experiences are insignificant in comparison.

J. HOLLAND.

T.T. RACES IN THE ISLE OF MAN.

Sir,—In a paragraph in your issue of the 30th ult. it is suggested that, owing to the uncertainty as to whether the T.T. course can be put into proper order, Ireland is the only alternative for a race this year. I do not know on what facts this paragraph is based. The truth is that the T.T. course, with the exception of one small part, is in as good condition to-day as it was in 1914, when the races were last held. That one patch—it is part of the mountain road—is cut up very badly, and I have talked the matter over with the Highway Board, which is responsible for the upkeep of the Manx roads, and the Board is ready, provided the A.C.U. signifies its willingness to hold the race, as quickly as possible to divert all work on other roads and to restore, and even better, the T.T. course, so that the races could be held here as in former years.

I trust that your influential journal will do what it can to assist in the reconstruction of the T.T. races. The Isle of Man has passed through a very bad time since August, 1914, and it wants every possible help it can get, otherwise the plight of the inhabitants, who have hitherto always given of their best to the motor races, will be terrible. I might add for your information that the Shipping Controller has already informed the Island that we shall have our boats back before June next.

Douglas, I.O.M.

GEORGE S. A. BROWN.

THE STRIKE BREAKERS. A Douglas owner makes good use of his sidecar during the suspended operations of the Tube railways.

TO KEEP THE HANDS WARM.

Sir,—A tip for winter riding: Instead of thick gloves, get a pair of fur or fleece-lined handle-bar muffs. They keep the hands beautifully warm, and one is free to make adjustments, etc., without the trouble of pulling off gloves.

E. W. R. PETERSON.

INFINITELY VARIABLE GEARS.

Sir,—Re your article on "Gears" by "Julius" in the issue of *The Motor Cycle* of January 23rd, I may state that I have patented a gear for either chain or shaft drive which gives ratios from 1 to 1 down to infinity (theoretically—practically it is a 1000 to 1), free engine and a reverse. Owing to the difficulties of obtaining material, etc., during the war, it has not been possible yet to test this sufficiently to market it, but the principle is one which has been used in the textile industry for years, and has given every satisfaction.

Now that hostilities have ceased, I hope to be able to place it on the market within a few months.

T. W. E. BROGDEN, LIEUT., R.A.F.

THE LIFE OF BELTS.

Sir,—I have found a very perceptible lengthening in the life of the belt when used on an infinitely variable gear if the belt ends are shaped to fit well home in the belt fastener, and a still further improvement if the belt fastener hook is wrapped round with a thong or belt lace. This soon shapes itself to the angle of the pulley, and when running on low gear increases the arc of contact very considerably, and does away with the "click" of the belt hook when passing the pulley, and if this thong is tied with a knot on the top the leather will last until it is time to shorten the belt again. I enclose a model, which may be of interest to some of your readers if sketched.

Coventry.

A belt-fastener tip recommended by "Various."

VARIOUS.

SPEED!

Sir,—In your issue of January 16th your contributor "Ixion" discourses on the "Hogbus" of the future, and makes the statement that an ex-R.A.F. pilot "accustomed to 150 m.p.h. will not be thrilled by slamming open his throttle with about $3\frac{1}{2}$ h.p. loaded up to about 4 cwt." Your contributor is evidently labouring under the same delusion as the said R.A.F. pilot, who very probably joined the Royal Air Force under the impression that he was likely to experience the joys of hitherto un hoped-for speeds. Surely enough has been written about flying to make it quite clear, that the 150 m.p.h. that is made by our single-seated fighters does not convey the feeling of high speed to the pilot unless he deliberately makes mental notes of the actual distance apart on the ground of objects over which he is flying, and the time he takes to pass from one to the other. Flying an aeroplane at 10,000 feet may be compared to sitting in a fixed aeroplane and looking down on a huge coloured map which is slowly passing underneath the machine. The first impression I got when I was "taken up" was that the machine was unable to make any headway in the terrible wind which seemed to be blowing. We barely seemed to be moving, and yet the air speed indicator registered fifty knots. The wind illusion was, of course, caused by the fact that I was in the propeller "slipstream." When landing, the nearer the machine gets to the ground the more speed it seems to acquire, although the speed is in reality being reduced from "gliding" to "stalling" speed.

Most aspiring pilots went in for flying with "Ixion's" delusions as to feeling the speed of an aeroplane, and as their instincts are not likely to change until they grow considerably older, they will probably demand some sort of "hogbus." I personally consider that the T.T. model, or its 1920 equivalent, will have a great vogue among ex-R.A.F. pilots. Young men of eighteen to twenty-one do not need kick-starters and four

speeds, and it is doubtful if many of them would care for the extra weight and expense.

I cannot agree with "Torque" that "losing one's prop" is a matter of small account at any time, and especially with a stationary engine. Does he know of any stationary that will restart purely from "friction of the air on the propeller"? As his article is extremely informative and well-written, he probably is speaking from actual experience, and, if so, I should like to hear about it as far as it concerns my point.

New Brighton.

REVS.

AN OPINION OF A WELL-KNOWN COMPETITION RIDER.

Sir,—Post-war machines! Many times have we read these words in *The Motor Cycle* during the arduous times just past, and considered them in many climes and many countries strange to the motor cycle.

Surely, if Mr. Manufacturer has studied the lessons which the war should have taught him, we shall get at least improvement of detail.

In the past we have been troubled with the small things on a machine; some fittings are "too flimsy," and in consequence cause trouble on the road, and by frequent renewal increase the cost of motor cycling. "Accessibility" is another point which needs careful investigation, and in my opinion the seller who can always point out to the buyer the simple way he can remove this or that, without having to interfere with something else, scores points all along the line. Problems of compromise, I know they generally are, but still improvement can be made with a little extra care and forethought.

The question of competitions is another post-war item, and we must look to the A.C.U. to give us something really instructive, and a more searching test than in pre-war days. How many entries would be forthcoming for a week's trial without tool outfit or spare (except tyre repair outfit) and standard machines taken from stock? A perpetual trophy, to be held for one year, should be put up for this event.

The future of the motor cycle is in the hands of the manufacturers, and the onus rests with them to place before the buying public a machine at all times serviceable and thoroughly reliable, with comfort and cleanliness combined.

W. PRATT.

ELECTRIC LIGHTING BY DRY BATTERY.

Sir,—The article, "Electric Lighting by Dry Battery," by "F.B.S." calls for a strong protest. I have no stake in the matter other than a keen interest in the pastime for its own sake, but I think that non-technical riders, who generally pay heavily for experience, should not be misled by such claims as the writer puts forward.

Leaving out of question the weight and inelegant encumbrance of any kind of battery on a motor cycle, one is compelled to state in definite terms that primary cells of any kind whatsoever are useless for electric lighting on a motor cycle. A dry cell that would last two years on a door-bell circuit would be such a good proposition that the "wet" Leclanché would cease to exist outside of museums. I will quote an instance of everyday dry battery service. Dry cells are used in appliances, "galvanic" sets, faradic coils, etc., for electrical massage treatment, almost to the exclusion of wet varieties, on account of convenience, and the currents normally used are measured in terms of milliamperes, yet their life is rarely as long as six months. Average discharge 15 mil-amperes, not $1\frac{1}{2}$ ampere for nine months.

"F.B.S." says his head lamp gives 6 c.p. and tail lamp 3 c.p. All I say is that if he can get 6 c.p. from a 4 watt lamp and 3 c.p. from a 2 watt lamp, he is indeed fortunate. Of course, to a motor cyclist who has cash to spare, a dynamo and accumulator are the finest lighting outfit possible, because as soon as the battery gives trouble he can throw it out and replace with a new one; but to the rider not so well blessed I say electric light is "off," because an accumulator is a *sine qua non*, and the accumulator has yet to be invented which will survive the strenuous conditions of service on a motor cycle, and a well-made acetylene outfit is quite reliable and cheaper.

In conclusion, I suggest that electric light has been boomed for motor cycles merely because a few like to emulate car practice, and partly because of the shortage of calcium carbide.

St. Albans.

PRACTICAL ENGINEER.

ALUMINIUM RADIATING FINS.

Sir,—I have been experimenting for some considerable time with a view to obtaining better cooling of motor cycles and other air-cooled engines, and have now perfected and provisionally patented a method of permanently uniting aluminium radiating ribs with a cast iron cylinder body.

It is a well-known fact that aluminium has a much higher conductivity than cast iron, the proportion being about $2\frac{2}{3}$ to 1 in favour of the former metal, and numerous attempts have been made to fit ribs to iron or steel cylinders. Any method of casting on or shrinking the ribs over a barrel is bad, as, upon heating, the aluminium having a greater expansion than iron becomes loose, thus destroying the metallic contact between the rib and the cylinder with a great loss of cooling effect. In my method the rib forms part and parcel of the cylinder body, being put into place during the actual moulding and casting of the cylinder.

The sectioned cylinders show the metallic contact to be perfect under all conditions; any temperatures up to dull red heat having no effect whatever, and on cooling or heating the ribs ring as sound as those on cast iron. The ribs may be made any depth, and as close together as desired, and it is impossible to separate them from the cylinder without tearing the aluminium or breaking the cast iron.

This construction marks a distinct advance in cylinder design: the aluminium ribs giving very much greater cooling whilst retaining the desirable features of a cast iron cylinder, and the rib being in perfect metallic contact with the walls, allowing a free and unobstructed transmission of heat.

The method should be of great value, particularly in the case of two-stroke engines. The extra cooling should make a vast difference, and to a great extent overcome the sticking up of the top ring due to carbonised oil.

EDGAR RUSSELL.

FUEL PRICES.

Sir,—Reading so much of the high prices of fuel, and the uncompromising attitude taken up by the different companies, I am surprised the powerful associations of manufacturers and owners do not take up the matter in a more practical manner. Suppose, for instance, the A.A. decided to supply its own members with petrol, and invited its members to supply the capital according to the h.p. of their motors. I do not think the Association would be long before it had all the capital required. Then with its system of scouts all over the country, it has the means of distribution already established, a percentage on the sales being retained by the purely tourist department of the Association, which would greatly reduce the wages account.

Surely something of the kind can be done. There is never a disease without a remedy, and we should be a poor lot if we put up with being fleeced by these big monopolies without making some effort. Although I only own a $3\frac{1}{2}$ h.p., my £5 or £10 is ready any time.

A. J. MALBY.

A SUGGESTED UNION.

Sir,—The majority of motor cyclists seem a very meek-minded lot, or long ago we should have had some something done to put a reliable fuel on the market at a reasonable price. Unless the industry is to be strangled, it is absolutely necessary that we should have this done without delay. The tens of thousands of returning men from the war, in the great majority of cases, cannot possibly afford to run a machine with fuel at the present fancy prices. With regard to benzole, I have just been experimenting with it, and find it far superior to No. 3 petrol, which is little better than

Section of a cylinder designed by Mr. E. Russell, showing the aluminium fins in position on a cast iron body.

neat paraffin. With "petrol" my combination rapidly heats up and will not take the most moderate hill without knocking and konking (unless dropped into bottom (!) gear), whereas with benzole, knocking and overheating quite disappear. Of course, the drawback to its use, in winter, is that it is impossible to start up on it. I have to inject No. 1 petrol (cold) or No. 3 (hot) to effect a start. The price charged, 3s. a gallon, is absurd. It could be sold at a good profit at 1s. a gallon, but it looks as if a "combine" had been effected, as one big company supplies both petrol and benzole (!), and so riders are bled for the benefit of the shareholders. What is wanted more than anything else is a strong motor cyclists' union, which could easily enforce fair treatment at the hands of manufacturers of fuel, as well as of machines and accessories. What excuse can be made, for example, for the way makers are charging £3, and over, for carburettors?

If a strong union were formed, with a nominal subscription (2s. 6d. a year would be enough), it would be a simple matter to obtain machines and fuel, etc., at a reasonable price, and, not only so, but the present numerous faults in machines would be rapidly eliminated. A general meeting once or twice a year in our largest towns would be quite enough to draw up the necessary requirements.

We want no more machines put on the road with working parts (wheel spindles, etc.) calculated at about 5% above breaking strain, and it is about time riders "got a move on" by taking action in the way I have named—forming a strong union. I can see no possible objection to the plan, though the trade might raise some, naturally. Making every allowance for extra cost of labour and materials, there is no excuse whatever, in my opinion, for the present-day fancy prices charged for fuel, for motor cycles, or for necessary accessories.

M. HITCHCOCK.

BENZOLE.

Sir,—I am in full agreement with "Motorist and Chemist's" letter criticising the N.B.A.'s fuel specification, and am quite sure that this specification has certainly never been worked out by any chemist who really understands either motors or benzole.

As he says, three shillings per gallon is too much to charge for this product, especially considering the price at which the Government have taken it.

His suggestion that the National Benzole Association should call a meeting of both chemists and engineers is a good one.

I think a benzole for fuel use would be quite good if made of 88% of 95's standard benzole with 12% 90's toluol to prevent freezing, and would give the producer an outlet for the toluol which now seems to be a drug on the market.

I find that a lot of benzole now being produced is going to the petrol companies, which is to be deplored.

As regards your remarks in "Current Chat" re poor benzole, I might say that there is absolutely no reason for this, as the quality should be a great deal better than that obtained pre-war, as the Explosives Department of the Ministry of Munitions have made the tests much more exacting, with the result that benzole now contains more benzene and less toluol in proportion than the pre-war 90% benzole.

I am pleased to see the prominence you give this subject, as this all-British industry should be encouraged, so that the price of petrol will become reasonable.

ANOTHER MOTORIST AND CHEMIST.

Wakefield.

[Licence-free benzole can now be purchased at 2s. 4d. per gallon.—ED.]

BOOKS FOR MOTOR CYCLISTS**HINTS AND TIPS FOR MOTOR CYCLISTS.**

A valuable collection of useful "wrinkles" and items of information concerning the running, management, and repair of motor cycles.

Price 2/- net. By post, 2/3.

TRACING TROUBLES.

Motor Cycle Faults, Their Identification, and Their Remedies Fully Explained.

Price 2/- net. By post, 2/2.

Obtainable by post (remittance with order) from

ILIFFE & SONS Ltd., 20, Tudor Street, London, E.C.4
or of leading Booksellers and Railway Bookstalls.

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Backfiring.

?

After about five miles running on my Scott at a good pace the induction pipe blows off. It is a 1911 model, with a Bosch magneto and a Scott carburettor.

Do you think I have timed the magneto too early? I have tried retarding it one tooth, but then the engine spits in the exhaust.—H.H.L.

The trouble may possibly be due to retarding the ignition too much, or to too weak a mixture. It is just possible that the trouble might have been due to an explosion in the crank case if the pipe was violently blown off, and this might have been caused by the absence of gauzes in the transfer port covers.

Magneto Conversion.

?

I have a spare magneto, and am thinking of fixing it on to my Morgan for a lighting outfit while the machine is running, utilising an accumulator when the machine is stationary. The armature being H section is, of course, useless for charging the accumulator, but, is it right that, with permanent field magnets, the voltage is not materially affected by the speed of the armature within certain limits? I propose removing the contact breaker and utilising the current off the low-tension part of the armature only, running the wires one from the cut-out and the other from earth. It is a car magneto. At what speed do you think would give enough current for five lamps?—T.W.E.B.

Although it is possible to use the primary windings of a magneto in this way, the output will vary a good deal with the speed, in spite of the field being produced by permanent magnets instead of electric magnets. There are some lighting sets made in this way, but the field magnets in that case, being much larger and more powerful, will ensure better regulation. There is no reason why you should not try it, however, and we should suggest that you gear the magneto so as to run at about 1,500 to 2,000 r.p.m. at the ordinary speed of your engine. We presume you intend to replace the long central screw after removing the contact breaker, otherwise you will not get a connection to the primary windings from the cut-out terminal. The best output is given at a speed of about 2,000 r.p.m., and at this speed the magneto will give a current of 2 amperes at four volts or 1½ ampere at six volts. Probably the best light would be obtained by using two six-volt four candle-power lamps in parallel.

Purchasing a Motor Cycle.

?

Could you give me your opinion of a 3½ h.p. Premier motor cycle? I am considering buying one second-hand for use with a sidecar.—D.R.A.

The 1914 3½ h.p. three-speed countershaft motor cycle (not a 1915 model, which was enamelled grey) was a good machine, as its records in the trials with sidecar testify. When buying second-hand, it would be advisable to remove the exhaust valve cap and examine the cylinder wall at the point where it is nearest to the exhaust valve seating, to ascertain whether this is cracked. Replacement cylinders are not obtainable just now.

Legal Query—Essence of Contract.

?

I gave an order about three weeks ago for a new machine, to be delivered in February, paying a deposit of £5. Since then I find I cannot possibly pay for it. I have written the agents, explaining that I cannot pay for the machine, and asking them to cancel the order, I forfeiting my £5 deposit. They have answered, explaining that they cannot cancel the order, and that when the machine is ready they will enforce payment. (1.) Can I legally cancel the order? (2.) What do you advise me to do?—G.R.

It is quite clear that you cannot cancel the contract by forfeiting the deposit, and the agents can make you take the motor cycle, or they could resell it and sue you for any loss sustained. If the motor cycle is really worth the money which is being paid for it, one would imagine you would be able to get someone to take the machine over at the same price; but it rather looks as if you have made a bad bargain, as otherwise one would think that the agents would be only too pleased to have the deposit of £5 and then resell to another party at the same figure. However, you have entered into the bargain, and must put up with the consequences if you do not pay. The proper course is for you to inform the agents that, having regard to the attitude they take up, you intend to carry out the contract, and will be glad to know when the machine is ready. You could in the meantime take steps to resell. You do not say what machine you have ordered, but if it is a good make you should have no difficulty in disposing of it, and getting someone to take the deal off your hands by completing the purchase, in view of the scarcity of new machines at the present time, at a good price.

READER'S REPLY.

In reply to the queries of your correspondent, "F.H.," in your issue of January 30th, re F.N. motor cycle, machine No. 35,757 was made during the year 1910. The F.N. multiple-disc clutch can be fitted to any fixed gear machine by substituting it for the existing flywheel and screwing a new front cover into the bottom bracket. The flywheel is screwed on a left-hand thread with a right-hand lock-nut, a special tool being required for its removal. A two-speed gear can be fitted between the bottom bracket and the bevel case in place of the plain driving-shaft and frame tube. Gears for converting old machines were made by Messrs. Horstmann, of Bath, but the only people now likely to be able to supply are Messrs. Robert Earl and Co., High Street, Hampstead, London, N.W. If the machine will not run slowly, make sure the distributor is clean, fit new inlet valve springs, and take great care to make all joints on the induction system perfectly airtight. Also see the exhaust valves are not sticking in their guides owing to burnt oil. Should your correspondent require any other information, I shall be pleased to give it.—ERIC CAUDWELL.

EXPERIENCES WANTED.

"A.W.N." (Hull).—4 h.p. Douglas and sidecar. Consumption, speed, and reliability.

RECOMMENDED ROUTES.

BRADFORD TO SOUTHPORT.—E.W.

Bradford, Halifax, Huddersfield, Rochdale, Bury, Bolton, Hindley, Wigan, Skelmersdale, Ormskirk, Scarisbrick, Southport. Approximately 76 miles.

LEICESTER TO COLWYN BAY.—E.B.

Leicester, Market Bosworth, Tamworth, Lichfield, Rugeley, Weston, Stone, Pipe Gate, Woore, Nantwich, Tarporley, Chester, Mold, St. Asaph, Abergele, Colwyn Bay.

ORPINGTON TO ROCHESTER.—H.K.G.G.

Orpington, St. Mary Cray, whence you can reach the main Dover Road, which follow for a short distance, then turn left for Sutton-at-Hone, Cobham, Cuxton, Rochester.

BRADFORD TO LEEK.—A.E.B.

Bradford, Brighouse, Huddersfield, Holmfirth, Holme, Woodhead, Glossop, Hayfield, Whaleybridge, Buxton, Royal Cottage Inn, Leek. Approximately 65 miles.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—First 12 words or less 2/-, and 2d. for every additional word. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd., and crossed** & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge, which must include the words Box 000, c/o "The Motor Cycle." Only the number will appear in the advertisement. All replies should be addressed No. 000, c/o "Motor Cycle," 20, Tudor Street, E.C.4.

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

Two Stroke Ivy Policy for 1919.

"Specialisation"

Having now completed our Munition and Aero contracts, we desire to advise you that we are manufacturing for 1919 our well-known Two-stroke only in four models. We are discontinuing our Popular Models and concentrating solely on de Luxe productions, in order to give the Motor Cyclist the finest engineering product obtainable.

Our programme is—

2½ h.p. de Luxe "All-purpose" Two-stroke, Single-speed - - - £42

2½ h.p. de Luxe "All-purpose" Two - stroke, Two-speed Gear - - - £50

2½ h.p. de Luxe "Isle of Man" Sporting Two-stroke, Single-speed - £45

2½ h.p. de Luxe "Isle of Man" Sporting Two-stroke, Two-speed Gear - - - £53

Sporting Models have Special Engines and Disc Wheels.

Deliveries start end of March

To
Agents

The Ivy Agency will be in great demand. If your district is not covered write us, as we are now fixing up territory.

The "All-weather" Motor Cycle.

OLD usages die hard, whether ridiculous in their application or not, and a case in point connected with the riding of motor cycles is the unjustifiable employment of the term "season." At all times of the year, in the cold days of January and in the broiling heat of August, the motor cycle is to the pleasure-seeker a pleasure and to the business man a boon.

"Many things by season, seasoned are to their right praise and true perfection," says Shakespeare, and, if in high summer the motor cycle is the best appreciated, it is no reason why we should continue to talk of motor cycling as if it were indulged in only during that particular period. The abolition of the term needs no greater justification than recent events provided. Whilst the Tube strike was in progress, hundreds of motor cycles helped in a small way to relieve the transport between the suburbs and the city. During the last spell of frost, too, the sidecars both for pleasure and business were much in evidence. At week-ends in the neighbourhood of big towns motor cycles are as numerous as motor cars.

True sport and real pleasure may be experienced in the rush of the biting wind, as well as in the soft breezes of summer; variety is the spice of life, even in motor cycling.

Neither is this "all-the-year-round" riding confined to the male sex. A sign of the times is observable in the keen enthusiasm of lady motor cyclists and sidecarists in every kind of weather.

It is from the riders who scorn to store their machines in winter that one gets the reasoned and sound criticism of weatherproofing, and it must be admitted that constructive criticism is the most effective way of drawing manufacturers' attention to riders' wants.

If the few motor cyclists who coddle their machines and themselves would brave the elements and cast "season" from their vocabulary, they could speak more authoritatively on subjects

pertaining to the pastime, and, incidentally, add greatly to their pleasures.

In talking of fishing, football, or cricket, the expression is sensible, it has a meaning, but to apply it to a mode of travel as universal as motor cycling is a reflection upon the all-weather qualities of the modern motor cycle.

Is a T.T. Race Possible?

AN invitation has recently been sent from Douglas, I.O.M., to the Royal Automobile Club to hold a car race in the island during the present year. The R.A.C. has given its approval and the decision now rests with the S.M.M.T. If a car race is held, is it too much to hope that a motor bicycle race might follow it? We have evidence that the T.T. course could be put into-excellent order by next summer, and the local authorities are prepared to put the work in hand at once.

The Islanders look forward to the races as a means of increasing their prosperity and bringing additional visitors to their shores. Sporting motor cyclists would doubtless vote unanimously for the resumption of the races next summer, but it is improbable that the trade will be able to devote their energies to racing and at the same time satisfy the numerous customers who wait impatiently for their standard models.

A race for private owners and despatch riders would, we have no doubt, receive a large amount of support, and, if well organised, would turn out to be a thoroughly sporting event productive of much good tuning and good riding, but it would hardly take the place of the classic event of past years; moreover, it is possible that without the assistance of the trade there would be great difficulty in bringing the event to a satisfactory conclusion.

Though we and our readers would like to see a race in the Isle of Man during 1919, we recognise that, in view of the very exceptional circumstances which prevail at the present time, the final decision must rest with the trade.

IDEAS: Useful and Ingenious.

By Ray R. Jones

AUTOMATIC LAMP LIGHTERS.

THE attachment of auto-lighter mechanism makes it possible to light acetylene lamps by a flick of the finger, like switching on electric lamps, on any night, windy or otherwise.

First obtain two sets of mechanism, consisting of wheel, holder, flint, spring, and adjusting screw, as used on ordinary pocket lighters.

To fit one to the rear lamp a piece of strip tin or brass is cut, filed, drilled, and bent to shape, and the lighter soldered into position as shown. A small slot is then cut in the side of the lamp to fit the wheel by drilling a row of holes and opening out with a file, so that the spark occurs about a quarter of an inch above the burner.

The lighter is then put in position on the side of the lamp, and the ends of the strip are bent to suit the contour of the lamp and riveted on.

In the case of the front lamp the lighter is put inside the lamp and operated from outside.

A piece of tin is shaped as shown, a hole being made to suit the screwed portion of the burner tube, and a smaller one in order that the flint, spring, and screw may be inserted after the body of the lighter has been soldered into position.

The lighter wheel is fitted with a spindle made of a cycle spoke, the end of which is filed slightly taper, and driven into the hole in the wheel.

A simply designed automatic lighter.

A hole is next drilled in the lamp case, so that the end of the spindle may project through. The projecting end of the spindle is then bent to form a small crank. Turning this crank in the correct direction will result in a stream of sparks being shot over the burner, which will not fail to ignite the gas in even the strongest wind. It is well to unfasten the door catch, in order that an explosion, if it occurs, shall not blow out the front glass.

The fitting placed in this position does not in any way obstruct the light.—H.D.H.

A12

AN ALTERNATIVE TO CARRIER STRAPS.

STRAPS are poor things at their best, frequently stretching and breaking at the precise moment when most needed, and, further, they are exceedingly difficult to manipulate in cold weather.

A really good substitute can be made from R.A.F. wire, or any good cable of that kind, and a pair of turnbuckles, such as are used for rigging an aeroplane;

Turnbuckles and R.A.F. wire as carrier straps.

these articles should be easily obtained just now. The approximate length being decided, the necessary splicing and fitting is an easy matter. Leather pads to protect the corner of the object carried will be needed, and may be neatly looped on the wire so as to slide to any position.

A board on the carrier, covered in felt, if a good suit case is being carried, is necessary to avoid chafing on the carrier bars. A few turns of the buckles and the wire can be drawn to the necessary tautness.—F.A.S.

SINGLE CONTROL LEVER.

ALTHOUGH of the single control type, this lever is used with dual cables and the ordinary two-slide carburetter; in fact, it is fitted in exactly

A new method of single lever control. The movement of the lever might be termed universal, and is similar in action to the "joy stick" of an aeroplane.

the same manner as the usual double control.

As will be seen, the horizontal motion of the lever determines the opening of the throttle, and the vertical motion regulates the position of the extra air slide.

It is obvious that innumerable mixtures and volumes can be obtained by varying the position of the control lever.

One might at first be inclined to believe that this compound motion is too complex for a standard handle-bar attachment, but it requires little practice to determine the best path of the control lever; and after using once or twice, the varying mixture that is required from, say, starting up to full load, can be operated by the thumb in one movement upward and to the right.—H.

AN EASILY OPERATED REAR STAND.

A PROPOSED solution of the problem of raising motor cycles, particularly the heavier models, upon their stands, without excessive effort on the part of the operator is here given.

"The method adopted is to interpose a lever between the cycle and its stand. The stand for preference should be of the double A variety, the upper portion acting as the fulcrum.

A rear stand requiring little effort of operation.

"The stand is dropped into position in the usual manner, the lever remaining in a horizontal position.

"By depressing the lever the machine is raised with a minimum of effort, and a spring clip attached to the lower portion of the stand retains the machine in position as long as desired.

"When not in use the whole device will collapse, and may be secured to the mudguard in the same manner as the ordinary stand, and it occupies but little more room.

"I find the arrangement is a great success on my Indian sidecar, and saves many an exhausting struggle.—B.B."

Occasional Comments

"By Ixion"

Strikes and Sidecars.

THANKS to the collapse of the London transport system I have been largely resident in a variety of sidecars for the past week, and they have suggested a whole series of points for study and experiment. One of the combinations was a 7 h.p. Indian, the sidecar being almost as large as a Blimp. This proved extraordinarily comfortable, but grossly unsociable: I sat on a cushion on the floor, and the Indian has rather a high saddle, so I had to give my muzzle 90° right plus 60° elevation whenever I wished to address the driver. I noticed with interest that the owner used his pilot jet exclusively in London driving, starting from rest on it, and travelling up to about 22 m.p.h. on top gear without opening the throttle. This secured rather an absurd adjustment, and, as acceleration implied a gear change, the pick-up was bad. I should like to conduct exhaustive tests on slow-running carburation for motor cycle engines; the majority rely on weak suction at a large jet, and better results should be obtained by fierce suction at a small jet. Another of my mounts was an A.J.S. s.c., which was normally driven in traffic on its lower gears, and gave terrific acceleration on an excellently tuned Amac. Its main defect was the absence of a spring frame: when crawling out in a traffic block, one could feel the back wheel dropping into Oxford Street pot-holes and clambering out of them exactly like a tank negotiating an old trench.

Two Methods of Traffic Driving.

THESE two machines showed up opposed methods of threading the traffic. The Indian driver adopted the principle of constant engine speed and used his gears for varying road speed. In favour of his methods, it may be urged that he created the minimum of noise, but gave himself the maximum amount of trouble, including much one-handed steering. The A.J.S. driver never used top gear unless he had a clear opening for a long sprint, but drove on the throttle with a lower gear engaged. The average driver combines both methods.

Air-cooled Engines—in Winter and in Traffic.

BOTH riders were obviously obsessed by their engines in two main respects. They got the wind up if they were blocked in traffic for a minute or two, and it is unquestionable that ticking-over in traffic does not suit pre-war air-cooled engines. At the same time you do not care to switch off, as the block melts quite suddenly, and a slight delay is involved even if the engine responds to the kick-starter immediately—which it cannot on present-day juice. Secondly, both of them were justifiably anxious about letting their engines cool when I made a call, lasting more than a minute or two, because restarting was so uncertain. The kick-starter seldom acts with a really cold engine on No. 3 spirit; prolonged pushing

and dope of aviation spirit or methyl-ether are the chief alternatives. It is quite clear that if fuel does not improve in quality by next autumn, artificial heat *must* be provided for engine starting; and the manufacturer who bears this point in mind will not regret it. There is no particular difficulty about water-jacketing the carburetter or inlet pipe, and a small spirit lamp for boiling the water could be carried. This sounds an extreme measure, I admit, but desperate occasions demand desperate remedies. Strong youngsters are having cruel struggles to start well-tuned machines of moderate weight. If nothing is done, the winter of 1919-1920 will see motor cycling under a cloud; and, if an electric carburetter heater is the most convenient panacea, our machines are not as yet furnished with the requisite current. Even if dynamo lighting is standardised during the ensuing year, it is not yet certain that the size of battery portable on a solo mount will stand the extra drain of heating the carburetter for repeated starts per diem. I think the eyes of some of our designers would be opened if they could spend a day in London just now with some of our girl D.R.'s and elderly male private owners. Engine-starting clouds their entire day in much the same way as an impending visit to a dentist's: and bad fuel is the root cause.

The Motor Thief.

THE second bugbear of Metropolitan motoring is the prevalence of theft. The burglars are as ingenious as they are daring. No car or cycle is safe if it is of a sufficiently common type to evade recognition during its hasty trip to the secluded workshop where it is camouflaged prior to sale. It is useless to change over the high-tension wires or put a disc of paper between the contact breaker points. Either the thieves are quite clever enough to diagnose such little tricks, or more probably a confederate keeps watch over the likely pull-ups, and cynically watches the owners while they take their innocent precautions. The only real safeguard is to own some weird-looking projectile or to dazzle-paint it in purple and yellow forked lightning, when the light-fingered brigade will be nervous of being tracked to their lairs. Here, again, the designer and accessory dealer have an obvious opening. As soon as bicycles lost their rarity and individuality, cycle thieving developed into a new "crook" profession, and anti-thief devices of an effective character came on the market. Similar devices are easily applicable to motor cycles, and the demand for them will be constant.

Sturdy Two-strokes.

JUDGING from one or two quiet digs in the Correspondence columns, I seem to have created an impression that I have no use for baby two-strokes. If anybody wants me to say that I regard them as having reached the standard of the 3½ h.p. four-stroke, I am emphatically a non-starter. This does not imply

Occasional Comments.—

that some of them are not really good: nor exclude the possibility that some of them are really bad. I can only generalise, and *pace* my critics, I will offer the following propositions for debate:

1. The baby two-stroke is simple in design; and consequently may attract the maker of cheap machines. Two-strokes are therefore of very mixed breed.

2. A well-tuned two-stroke is an incredible glutton for work. As tuning involves very accurate setting of the carburation and ignition, and is performed at best with a very narrow safety margin against overheating, it is not every buyer who gets delivery of a well-tuned mount. Neither is every buyer capable of tuning a two-stroke. An ill-tuned two-stroke may balk after three miles at 25 m.p.h. on the flat

Experiences as an Owner.

I HAVE owned perhaps a dozen baby two-strokes, some of them good and some of them horrid.

The main problem with all alike was to find a plug which they could not render incandescent up a long hill: aero plugs seem to suit them, and, as these plugs are now released for public sale, I think the babies will grow more popular. In the second place, they need running in: "baked" top piston rings occur readily with many of such engines, implying that overheating is never far distant; if any part is tightish, trouble occurs till a sweet-running fit is obtained. Thirdly, you have to learn on the road how to wangle the lubrication, which is never automatic and always affects carburation. Fourthly, the lilliputian type of carburetter is peculiarly liable to flooding, whilst an over-rich or a lean mixture accentuates the risk of overheating. Consequently, if a duffer buys an inferior make of two-stroke, he is usually in for trouble in the flesh; but if he is keen and teachable, he survives it, and when

"tune" is obtained, his little mount develops into a reliable glutton for heavy duty. On the other hand, if he is dull-witted and saddled with an ill-tuned or ill-made or ill-designed machine, he gets thoroughly disgruntled inside 1,000 miles. Here is my gospel for would-be two-strokers:

1. Get a cool plug.
2. Run the engine in patiently.
3. Oil it very accurately.
4. Play with the carburetter till it is right.

This same gospel is freely expounded in an excellent pamphlet of two-stroke tips supplied gratis to applicants by Messrs. Brown and Barlow.

The Post-war Two-stroke.

I AM fully prepared to recant all the above caveats within twelve months—they are only written with ephemeral conviction. Five years of concentrated progress in air-cooling lies behind us, and we have yet to welcome the post-war baby two-strokes. Unless they are designed by engineering ostriches, whose heads have been buried in the sand since 1914, they will be far less prone to overheat than their prototypes. For example, a certain maker of air-cooled engines used to warn his clients never to run his engines free for more than sixty seconds; three years later he successfully ran one of his own engines free and fanless for four hours. Embody these modern principles in a baby two-stroke, and the four maxims laid down above are deprived of all urgency. Any old plug will serve a cool engine. Stiffness when new does not matter if you have a large safety margin in temperature. If an engine is air-cooled, you need not use oil-cooling as

an auxiliary, and you will not risk upsetting the mixture by converting the cylinder into an oil-bath for the piston. If the temperature is reasonably low, a fat or lean mixture will not produce seizure. So I am full of hope.

The idea of restricting motor cycling to a "season" is now dying a natural death in the United States, and, as in England, motor cycling is indulged in all the year round. The photographs—taken in the U.S.A. a few weeks ago—show Indian outfits in a district which might well pass for a Yorkshire scene, with its typical low stone walls. The expedition was clearly a sporting one.

Reporting the T.T. from the Air.

Possible Use of Aircraft in Journalism.

AT the moment it is doubtful whether the T.T. will be held in 1919, and if so what venue will be available. In any case, the next race, like its predecessors, will be run "over the water." Our readers may not have realised that to publish a fully illustrated report of the race at all promptly implies "some" rush. The afternoon boat leaves the Isle of Man just about the time at which the race finishes. The cable is pretty well blocked with press telegrams, and it is impossible for any one journal to wire thousands of words immediately. Consequently several of our staff, laden with heavy boxes of negatives and fat notebooks full of hasty jottings, board the boat at the last moment. The afternoon boat is not always an ocean greyhound: the s.s. *Ben Machree* was the fastest of the I.O.M. Steam Packet Co.'s fleet, and she took over three hours to reach Liverpool. If some of our party who deal with the actual finish of the race and obtain full times from the judges are delayed till the midnight boat, the voyage will probably take them six or seven hours. When the pressmen at last land in Liverpool, the trains are invariably awkward, and in consequence fast cars meet them at the Prince's landing stage, and convey the negatives and copy to our printing offices.

For the next T.T. a service of powerful aeroplanes may be employed. Busy men and habitual victims

of *mal de mer* will cross by aeroplane. Competing firms will transport urgent spares — possibly complete machines — by air. The crossing would only occupy from forty-five to sixty minutes, according as a fast D.H.9 or a weight-carrying Handley Page was employed. It is more than probable that *The Motor Cycle* staff may make the return journey from Douglas

to Coventry by air in one stage, bringing their manuscript and photographs with them. Very little motion is experienced in the fuselage of a giant four-engined machine, and within a year or two newspaper associations will probably retain giant machines for urgent press reports of distant events. There is no reason why such a machine should not embody a dark room in which plates could be developed and prints made. Literary representatives could carry portable aluminium typewriters with them, and polish up their reports far more comfortably than is possible in a train.

Advertising or administrative stunts of an aerial character are also likely to be associated with future T.T. races. For example, a big tyre firm might elect to charter a small airship from which a representative could watch the progress of the race, wirelessly reports to announcement boards erected at the points where the chief crowds collect. Thus if the leader in the fifth round stopped to mend a puncture on the mountain, ten seconds later all the controls would hear "No. 7 mending back tyre one mile above Goose Neck," and so on.

Indeed, it is extremely probable that in a few years every illustrated journal of a topical nature will employ one or more pilots on its staff, and maintain its own aeroplanes. Modern journalism relies on the camera, and takes a pride in producing photographic reports of big events within a few hours of their occurrence. Every known form of swift locomotion was utilised for these high-speed stunts before the war — racing cars, motor cycles, motor boats, and special trains. Aeroplanes will often render possible feats which were impossible with trains and

Reporting by wireless the various incidents of the race

Preparing copy and developing plates as the plane speeds on its way.

Reporting the T.T. from the Air.—

steamers and motors. At present aeroplanes would often let the pressman down. Night flying is in its infancy, and what the Navy describes as "poor visibility" is a sad nuisance in long-distance daylight flying. In five years improved instruments should render the aerial navigator master of almost all conceivable weather conditions. When that day comes,

the most important illustrated daily journals will unquestionably keep a small fleet of high-speed 'planes, steered by crack pilots, and containing lilliputian dark rooms. In the meantime summer events, concluding in daylight, such as the T.T., offer a fair field for aeroplane organisation; and I shall be surprised if our next T.T. report does not enlist the services of a pilot.

ROAD RIDER.

CLEARING UP. A scene in France during the Allies' advance into Germany. The motor cycle in the foreground is a B.S.A.

Government Sale of Motor Cycles.

A Reader's Disappointing Experience during his Search for a Bargain.

THE bargain hunting car buyers are evidently suffering as badly as the motor cycle merchants at the Government sales, judging by the prices obtained for the rusted and mud-caked remnants put up for auction. It cannot be denied that a great deal of disappointment has been caused among the many prospective purchasers of motor cycles by the excessive and oftentimes ridiculous prices; but this provides an obvious lesson. There is a clear indication of a large market for a cheap machine, and of the existence of a great number of ardent would-be motor cyclists of mechanical turn of mind with very shallow pockets. Twenty-five pounds is their outside limit on a cash-down basis, and if they could buy one of the Army discards at from fifteen to twenty pounds and put it in order for another ten they would be well content. But it is not to be. The published prices have deterred many bargain seekers from visiting the sales, and the following gives an idea of the impressions of two men who went with the mistaken idea of getting something cheap.

The Trusting Optimists.

"Whilst on leave, I happened to run across an old motor cyclist chum, who suggested we should make our way to the Brixton Garage, where Aldridges were holding an auction of Government stock, including forty Douglasses. The prospect of getting hold of a good machine cheaply, as I foolishly thought, naturally appealed to me, as for some time past I had been looking out for a machine against the time when I should get my discharge.

"We found we had sufficient 'ready' between us (strange) for a deposit should we buy anything, and off we went.

"We arrived there just as the auctioneer had started selling the cars. After a lot of trouble we succeeded in obtaining a catalogue, and made our way to the motor bicycles, where we found a good crowd.

"We went round, making a note of our prices on the catalogue. We had priced about a dozen, and on reaching the thirteenth I said to my chum, 'Shall I put the same down for that?' 'That's right,' he said, 'throw your money in the air; the darn thing has no gear box, nor a contact breaker in the magneto.' We found lots of them minus various parts, such as gear boxes, contact breakers, valves, etc., and on one we tried we found no piston in one cylinder and the timing wheels gone.

"At last we had seen the lot, and 'starred' one or two we rather fancied. By this time we were beginning to feel hungry, so off we went to get something to eat. On our return they were just about to start on the sale of the motor bicycles.

"A hush went through the crowd. 'Lot 108, Douglas motor cycle,' said the auctioneer, 'what can I say for this?' The bidding started, and the motor cycle was knocked down for £29. We had put our price at £20. Others were put up, and mostly fetched £10 more than we calculated.

"In one case, one we estimated at £10 fetched £26, and a voice from the back cried out, 'Put a chain on him; don't let him get away'—a remark which I silently seconded.

"After seeing about thirty go we decided that sales were no good to us, and we had better look out for a push bicycle. We departed, cold, and thoroughly fed up. On leaving, I shook hands with my chum, and remarked, 'Never suggest another Government sale!'—KYN."

MOTOR CYCLE HORNS & SIRENS

A Study of the Mechanical and Psychological Problems of Warning Devices.

NINETY per cent. of the antagonism of a section of the public towards motorists as a whole is said to be brought about by the injudicious use of violent and raucous road clearers, and this can be well understood.

The basis of any appliance of the nature of a road signal has two important aspects—psychological and mechanical. The former is brought about by the fact that every person surrounds himself, or herself, with a wall of partial insensibility. For the greater part of the time he is unconscious with regard to his surroundings, and not fully aware of the dangers which beset him in the street. The depth of this preoccupation, and consequently the speed of perception and reaction, varies with each individual, so that signals must be designed to have effect on the least responsive.

The Ideal Signal.

It must be borne in mind, however, that the mere creation of an unusual sound will not always serve as a warning. The ideal signal must be distinctive and impelling, and assert itself above all incidental street noises. In addition it must satisfy the requirements of an emergency alarm, and at the same time act as a distant cautionary warning. In the first case, then, it must necessarily be loud, abrupt, and perhaps disagreeable, but not so much so as to cause a temporary paralysis of movement. Careful riding should, of course, largely prevent the necessity for such emergency use. The second feature demands that the sound have carrying power, be fairly directional, and sufficiently concentrated to a narrow zone of influence. To turn to the mechanical side, it may be stated that, like other accessories, fifty per cent. of these instruments virtually undergo a breakdown test, receiving, as they do, little or no attention at the hands of the rider until they fail in some way, which accounts for the many ineffective devices one sees in common use. That is the fault of the bothersome human element, and should impel the makers to make the mechanism practically self-sustaining and foolproof.

The Reed Horn.

The reed type of horn was universally adopted on motor vehicles about 1903. In these instruments the sound emitted by the reed is generally strengthened by resonance. The term resonance signifies vibration. The ideal resonance is where both sounding and responsive elements possess the same natural period of vibra-

tion. The resonator, therefore, reinforces the tone, or the reverse. In the case of sirens, however, the resonator is of no fixed pitch, and only attached for the sake of appearance. In the mechanical horn the resonator should have a pronounced natural frequency. The air column within the resonator affects to some extent the natural frequency of the diaphragm, and obviously the effectiveness of the signal will be enormously

The simple reed horn. This particular design was used by many despatch riders.

increased when the natural frequency of the air column is selected so as to be the same as the normal full speed note of the bare diaphragm.

But, to return to the subject, very few reed horns are effective in the rumble of traffic, and will not carry any great distance in the open country. They are also affected by the temperature to some extent.

Sirens.

The siren was introduced about 1905, and found but little favour with motor cyclists. It consisted generally of a hollow rotor contained in a casing, and was operated by the contact of a friction wheel with the front tyre or by a geared-up handle.

Section of an electric horn.

Exhaust Whistles.

These were found on some machines as far back as 1908, and have enjoyed a kind of sporadic popularity ever since. They are fitted to the exhaust pipe between the valve and the silencer, and are operated either by a plunger or some kind of disc valve. They owe their popularity to two causes: a continuous blast, but one varying in intensity, is obtainable, and the note is generally musical. Another form is connected to the exhaust pipe after the silencer.

The Electric Horn.

The electric horn is a diaphragm horn in which the diaphragm is caused to vibrate by the influence of electro-magnets. In the simplest form, the diaphragm itself, being of soft iron, is attracted by the electro-magnets, and, carrying one of the contact points to the electric circuit, serves to make and break the current. When the circuit is closed by pressing the button, the magnetic pull draws the diaphragm towards the magnet. The movement of the diaphragm, as will be seen, breaks the circuit, and the elasticity carries it back to the contact, thus reinstating the circuit. The series of operations is, therefore, continuous, and produces a sustained note.

The Electric Buzzer.

A modification of the above is the electric buzzer, which operates by the action of a hammer, similarly to the clapper of the electric bell, a diaphragm taking the place of the gong.

These types are generally operated by a six-volt battery, and, therefore, are not greatly favoured for motor cycle use.

The Mechanical Horn.

In the mechanical horn, the vibration of the diaphragm is accomplished by purely mechanical means, and the later types have proved exceedingly popular. In the centre of the diaphragm is a solid knob of metal, arranged to receive the impulses from a cam wheel or rotor. The total movement of the diaphragm is not more than five-thousandths of an inch, so that it can be operated very rapidly. The cam arrangement is rotated by a variety of means; in some cases a wheel is used, geared to a rack which carries a handle. When the speed of the rotor or number of cam pushes is properly harmonised to the vibration of the diaphragm, the ear perceives a recognisable musical note. Otherwise, when the dia-

Motor Cycle Horns and Sirens.—

phragm is continually overloaded to make a piercing sound, its life becomes considerably shortened. For this reason, the construction and design of a good mechanical horn is not so simple as it first appears. Some diaphragms crack and crystallise in less than a thousand signals. While the hand horn has the advantage of not being dependent upon any source of external energy, its position on the machine is limited. It should

A very simply designed mechanical hand-operated horn.

not interfere with the operation of any of the controls. Some riders prefer to have it attached to the footboard and work it with the foot, but then it must be so arranged that it does not occupy the foot which is required for the brake pedal, and if attached to the bars it should be on the opposite side to the exhaust lifter. Probably the best place, however, is on the top tube, where it can be got at with either hand; but this, too, is a nuisance on greasy roads, necessitating, as it does, the removal of the hand from the bars.

It would appear, therefore, that in nearly every respect the hand-operated diaphragm horn, if properly designed, is the ideal form of signal. During the period of action in which the rotor is getting up to the speed and into the phase with the natural period of the diaphragm, there is produced a disturbance that is entirely unharmonic, which, because of its peculiarly rough and abrupt character, is both distinctive and alarming if heard close at hand, and is thus suited to the purposes of an emergency signal. Unfortunately, many types are made on pure guesswork, and their tones are horrible, without being very effective.

The abuse of signalling devices is not only an annoyance to the public, but breeds confusion and tends to cause

signals to be ignored, thus defeating the interests of safety. The value of a warning signal is seriously impaired by the fact that it is frequently used for the purpose of a door bell, when the machine is standing by the kerb; as an alarm clock for sleepy garage attendants; and as a plaything for street urchins. In a sense, the warning signal may be said to constitute the only bond of common interest between the motorist and the public in its peculiar function of guarding the public safety, therefore it is deserving of more attention than it has received heretofore. MASCOT.

The Kirby mechanical horn.

Opinions from the U.S.A.

An American Correspondent chats on British and American Machines.

At least one American motor cyclist does not believe that the U.S.A. motor cycle has always led the product of this country in the evolution of design. This gentleman, in writing to us from Newark, N.J., gives the British industry the credit for the introduction of, among other things, flat twin engines, footboards, gear boxes, kick starters, sidecars, and front wheel stands, and points out that all the U.S. industry can point to seems to be electrically-equipped mounts.

Our correspondent is very enthusiastic concerning the new A.B.C., and asks

why, "for the affections of Michael," the makers cannot put it on the market at an attractive price. "Singular thing," he writes, "the Harley-Davidson Co. are busy with a 'sport' model flat twin that eliminates the short drive chain, as does this new Firefly motor. Speed the day when we can abolish messy chains and have all shaft drive, silent and clean. I wonder if it is too much to expect on a motor cycle."

"Your Triumph single must be a 'cuckoo of a mount,'" our friend continues in pure American. "Three friends of mine—American D.R.'s, who have

ridden two or more British mounts—simply rave when they describe the actions of a W.D. Triumph. One lad says it is the first real motor cycle he ever straddled."

We are informed that there is every evidence that there will be a big revival of sport in the U.S.A. this year, but the industry appears to be composed only of the Indian, Harley-Davidson, Excelsior, Henderson, Cleveland, Thor, and Reading Standard companies. The Smith motor wheel is still going strong, but the Merkel and Cyclemotor have dropped out, as has also the Emblem.

An Expanding Pulley Gear.

In a recent issue of *The Motor Cycle* we described an ingenious cycle car designed and built by a pioneer motorist, Mr. Leonard Jones. At the time of our visit to the inventor's workshop, details of the gear were not available, as the patents were not complete, but we are now at liberty to deal with it.

The drive is conveyed from the engine by enclosed chain to the countershaft, on which is mounted an expanding pulley. Over the rear axle, which is practically identical with that fitted to the old Ariel trieyele, is mounted a similar pulley, the drive being conveyed from one pulley to the other by belt. The chief novelty in the gear lies in the fact that ball-jointed toggle arms are employed for the purpose of shifting the movable flanges. The change-speed lever is connected to a sleeve on the countershaft. Inside this sleeve works a smaller sleeve, which is adjacent to the movable flange. The two sleeves are connected to the toggle arms

The gear as fitted to a cycle car

before mentioned, and the whole coupled up to a similar arrangement on the other pulley by an adjustable rod. The two sleeves which carry the flanges are also connected by a forked rod which prevents their rotation.

By means of the adjustable rod the toggles may be moved toward or away from one another, regulating the relative opening of the flanges, and so tightening or slackening the belt, as the case may be.

In the illustration, the position in one of the lower gears is shown. Naturally, to raise the gear the forward pulley is contracted, and the after one is at the same time automatically expanded.

In consequence of both pulleys being of large dimensions, the belt should wear a long time; the fact that it is adequately protected from wet also tends to prolong its life and prevent any possibility of slip. On the particular vehicle to which it is fitted the gear gives a very smooth drive.

A FLEET STREET COURIER.

THE MOTOR CYCLE AS AN AID TO DAILY JOURNALISM.

IF you are one of those Bohemian and poverty-stricken men who earn a precarious livelihood in Fleet Street (and I do not suppose you are), you will understand that there is no discipline more exacting than that which emanates from the Editorial chair. You can be hail fellow well met with any master of the blue pencil and scissors while there is nothing doing, but when you are bidden to get on to a story, you "get," and you do it quickly. And that's that.

On a pitch black night, and a rainy one at that, I was busily dopping a new war model Triumph with a particularly evil-smelling overcoat of grease, when the office boy ran down from the office to inform me that the Editor of a big London paper awaited my ear at the telephone. A minute later I was under orders to leave at once for the north-east corner of Norfolk, armed with whatever I needed, to get an illustrated story that had uninvitingly located itself in that particularly inaccessible place. All that I needed meant myself and an expert photographer to illustrate the story, seeing that a word picture would be inadequate without pictorial representation of the facts. It was past five o'clock, and I was advised that a train left Liverpool Street at 5.20. A glance at the A.B.C. showed me that that particular train was in no hurry to get to its destination, and that when it did, it landed me six miles from the end of my journey. Then I looked at the trusty Triumph, and fetched out the road map.

Stirrups for the Pillion Rider.

I am no believer in pillion riding, but there was only one machine and two men, so it had to be done. It was necessary to warn our respective domestic circles that we should be away, and, as we lived in different and difficult parts of London, it was three o'clock in the morning before we were ready to start—and still it rained. I had scraped together all the old overalls and impedimenta that I could find, and was done up like an inflated scarecrow. The pillion rider was likewise garbed, with the additional and *bizarre* fitment of brown paper leggings tied up with string. He had superimposed two cushions on the pillion, and had fastened a pair of stirrups to add to his comfort, and let me say at once that if you must ride on the carrier, fit stirrups—they are worth it. After about twelve miles of impossible cobbles and sticky tramlines, we touched the open road at Waltham Cross, and found matters worse.

There was mud in *excelsis*—inches of it, and in the first hundred yards or so we decided that it would

IN SEARCH OF NEWS
AND PICTURES
FOR A "DAILY."

The journalist and photographer about to start on their 100 miles ride from London to Norfolk.

not hurt us so much when we fell if we dropped to a slower speed. For about forty miles we carved a way through the mud without disaster, and then dawn began to break, so we opened out a bit, and made Cambridge in just enough light for mine host of "The Bull" to ponder over the advisability of admitting so disreputable a pair. Honeyed words from my passenger worked the oracle, however, and we entered. After a hearty breakfast we set off again, and, with drier and better roads, whizzed eastwards through Ely to Downham Market, which is the centre of the muddiest roads in the kingdom. Another hour took us through

King's Lynn to Sandringham, where royalty was in residence. Indeed, it was in attempting to make a courtly bow to Her Majesty of Norway, who with H.R.H. Princess Victoria was walking through the village, that the pillion rider nearly unshipped us. Sandringham is pretty, but it is a diamond in a quagmire. There are pinewoods which remind one of Hampshire, and there is a smell of ozone, which came as a pleasing contrast to the odour of loam and fertilisers which had offended our nostrils all through Norfolk.

Asleep on a Motor Cycle.

We accomplished our task in an hour or so, and immediately set back for the Metropolis, lunching on the way at Downham. I can always sleep well after a hearty lunch, and so, apparently, could my passenger, for we had gone but a matter of twenty miles when he sagged over on to my back and snored unmusically. The next thing I remember was that I had a dig in the ribs from the now wakeful passenger, with a demand as to why it should be necessary for me to negotiate a level crossing at thirty miles an hour—and I did not know we had passed one. I was more wakeful after that, but the pillion rider was not, and in his wakeful moments he exploited with fine rhetoric the alluring comfort of wayside hostelries and the dread crash which was the fitting sequel to overdoing it on muddy roads. But I had a mind to be through with the job as soon as possible, and after a while he discovered that he could not turn me from my purpose, and once again reverted to his snores. Darkness fell as we entered Ware, but we stuck to it, and, fifteen hours after leaving London, we were back again with about 250 miles to our credit and a coating of mud which would have made a decent sized allotment. My companion brightened considerably at the prospect of bodily comforts, and he has now placed an order for a machine similar to mine.

L.H.C.

Experiences with Seven Different Machines at Home and Abroad.

By GEORGE F. HALLIDAY.

The author of the following article is an engineer, and was a winner of one competition in connection with our recent "Which Type" referendum. His specification came nearest to the sidecar aggregate, and was based on experience with many types of machines in England and South Africa.

THE factors which led to my suggesting the specification for a sidecar machine, which was found to be the nearest to the aggregate in the "Which Type" referendum were based on conclusions drawn from riding experience on many different types of machines, solo and with sidecar, which were owned by me during the last six and a half years.

Backed up by an intimate technical knowledge of engineering practice in general, and that appertaining to high speed internal combustion engines in particular, my motor cycle experience has been conducted more or less as an experimental hobby.

As my journeys of the last four years have taken me to one of the colonies where conditions are entirely different from those existing in England, a broader view of general requirements has been acquired than would otherwise have been the case.

One of the first motor cycles I owned was a Rex. This outfit had competed in an A.C.U. six day trial. It was reluctant to start, but, when it did start, it went and took some stopping.

I had not had this machine long before I was on my way to South Africa. My destination was Johannesburg, a town abounding in motor traffic. Soon after arriving I acquired my second Scott, which, incidentally, was running on an alcohol-ether mixture when taken over. This machine ran very smoothly on the treacherous sandy roads outside the town and had a fine turn of speed, but, as is usual with this type of engine, fuel disappeared rapidly.

Belt and Chain Drive Machines.

Having occasion to return to England for two months I sought out my old Rex and made an exchange deal for a brand new Rex outfit which was ridden 1,000 miles in England before taking the combination to South Africa.

It must be said that, although this machine had a direct belt drive from engine to Roc hub gear, the whole sidecar outfit was of very robust construction, and when tuned up as a top gear machine it took a lot of beating. When new the engine was excellent, and having an adjustable pulley much experimenting was done with different gear ratios. Usually it was geared $3\frac{3}{4}$ to 1 on top for ordinary work using a $1\frac{1}{8}$ in. belt. This outfit used to cover the thirty-five miles

between Johannesburg and Pretoria regularly in seventy-two minutes or thereabouts.

The outfit was sold in favour of a $3\frac{1}{2}$ h.p. twin James, bought primarily for solo riding. With all the rigid scientific arguments in favour of the horizontal opposed twin—and these the writer fully appreciates—the engine of the twin James takes some beating in "practice." The only points which it is thought require attention are the gudgeon pins, which are rather small in diameter, and the single bush twin big end is not a very good principle in the writer's opinion, although it is admitted it is difficult of substitution in a small engine. The quick thread method of operating the clutch is not too good for colonial machines, as the sand soon makes it difficult to work. A stepped helix after Sunbeam practice is better, and though in hand-controlled clutches the long lever operating the push rod is simple, for compactness and good design the recommended system is better and more reliable.

The Effect of Altitude.

This machine was a great favourite and very much admired, because of the state in which it was kept; the plating and aluminium were maintained in brilliant condition (this is more easily achieved in the dry clean colonial climate than in England) and the machine in equal tune. In top gear the speed range of the James was between eight miles and fifty-five miles per hour; at the former speed the engine would fire perfectly regularly without falter, and it would always average over 100 miles to the gallon. In an over-estimation of the machine's capabilities a sidecar was attached; with this weighing 120 lb. and a passenger weighing eleven stone, the machine successfully negotiated over a quarter of a mile of average 1 in 8 on top gear. The combination was taken down to Cape Town during a two months' vacation, where the difference in power developed was noticed compared with the Johannesburg district, where the atmospheric pressure is only four-fifths that at sea level. Machines sent from England to such districts should have an engine with a higher compression ratio than normal, thereby counter-balancing the otherwise lowered compression pressure.

Fitting a sidecar to a machine designed for solo use

A Paying Proposition

for every Motorist and Motor Cyclist.

"The Amateur Mechanic," written by skilled craftsmen in simple, non-technical language, and practically illustrated by helpful illustrations, is now in constant use by over 35,000 citizens. With this "handyman's guide" at your elbow, you can

Teach Yourself How To Overhaul and Clean Your Motor

and to do simple repairs to motor cars and cycles. Also

To Do The Home Jobs That Cost Money.

The article on OVERHAULING A MOTOR CYCLE has many helpful illustrations, and the following titled sub-sections: Summary—The Wheels—The Frame—The Tanks and Fittings—The Carburetter—How the Engine Works—Overhauling the Engine—The Driving Gear—The Ignition Apparatus—The Brakes—The Reassembling, etc. This is money-saving knowledge for readers of this journal. The article on OVERHAULING A MOTOR CAR has also money-saving value for readers. This article has thirty-nine practical illustrations and drawings: also the following titled sub-sections: Summary and Explanation—Preliminary Examination Principally by Sight—Bearings—Carburetter, Couplings, etc.—Flywheel, Clutch Fork, etc.—Gauge Gear, Steering Gear, etc.—Frame Springs—The Ear Test—Testing the Engine—Compression Testing—Testing with the Engine Running—Worn Bearings—"Knocking"—"Popping"—"Hooting"—Silencer at Fault—Clutch—Change Gear—Undue Heating of Circulation Water—Lubrication—Testing on the Road—Ignition—Valve Timing—Defective Compression—The Shafts. A COMPLETE OVERHAUL: Testing for Alignment—Swivel Bearings—Wheel Bearings—Tyres—Removing Valve Chamber Covers—Removing Flywheel—Grinding in Valves—Removing the Engine—Testing Truth of Pistons—Removing Flywheel—Timing Gear—Magnet—Gudgeon and Pins—Case Hardening—Removing Piston Rings—Engine Repairs—Testing Bore of Cylinders—Truing Brasses—Belling the Crankshafts—Big End Bearings—Renewing Clutch Leather—Ball Bearings—Gear Renewings—Oiling Axle Springs—Aligning Gear Box and Engine—Reassembling—Engine Accessories—Brakes, etc.

"The Amateur Mechanic" also gives plain directions on—

How to paint and paper a room—To sole and heel and patch boots and shoes—To mount maps—To bind magazines and to re-bind old books—To make a pair of hand-sewn boots—To restore colour of old brown shoes—To make household furniture—To re-seat chairs—To upholster sofas, etc.—To install a speaking-tube—To make a wire bracket for placing over oil lamp or gas bracket so that food can be heated over it—To clean a Primus or other stove burner—To repair bicycles—To overhaul a motor car—To repair motor cycles—To work in metal—To colour metals—To make a garden frame—To repair water taps—To varnish a violin—To remedy damp walls—To repair the piano—To make a padded chair from an old cask—To make mailcart and perambulator hoods—To mend penknives—To stuff animals—To dress furs—To stuff and mount birds—To do wood inlaying—To cure a smoky chimney—To prepare working drawings and how to read working drawings—To make a chemical weather-glass—To renovate a grandfather's clock—To make invisible ink—To make garden furniture, arbours, arches, seats, summer-houses, tables, etc.—To use metal-drilling tools—To clean bookcovers—To renovate mirrors—To upholster furniture in leather cloth—To mend broken chiao—To do fretwork—To build a boat—To make a canoe, etc.—To lime-wash poultry houses—To do gold-plating and silver-plating—To clean a watch—To mend keyless watches and ordinary watches—To distemper ceilings and walls—To make picture frames and to frame pictures—All about curtain fittings—To make metal castings—To make tracing paper, waterproof paper, fire-proof paper, etc.—To clean paint off glass—To fit up a motor workshop—To clean boilers—To fix an anthracite stove—To re-gild and restore picture frames—How to use spanners—To make doors and windows draught-proof—To paint walls—To make a garden path—How to do nickel plating—To cure noises in hot water pipes—To make soap at home—India and glue varnishes—To clean and repair locks—All about acids for etching metals—Micrometers, how to make and use them—How to make plaster casts, etc., etc.

With Over 4,000 "How-To-Do-It" Illustrations.

This Work has helped others: it will help You.

It is a real "Enquire Within" on How to save Money in the Home.

Mr. JAMES MOORE, Gloucester, writes:

"The work is a splendid example of thoroughness, and a complete self-instructor. I consider it quite bears out what you claim for it."

Mr. G. LANCASTER, Waterfoot, Lancs., writes:

"I think they are well worth the money. They give me every satisfaction."

Mr. T. G. RIORAN, Upper Tooting, London, writes:

"With absolutely no knowledge of the trade to guide me, after reading the articles on Boot-making I was able to make a pair of boots, partly hand-sewn and partly riveted—and to make them well. Since then I have made a very fine pair of lady's shoes. I consider that nothing I can say about the work could be too much praise."

Mr. CARDWELL, Belfast, writes:

"They are splendid value . . . I cannot explain how pleased I am with the books. I shall recommend them to all my pals."

Mr. FREEMAN, Poplar, E., writes:

"The work is of great help to those who seek information on any subject, and is good value for the money."

OUR FREE BOOKLET.

Address

M.C.N. 1919.

In answering this advertisement it is desirable to mention "The Motor Cycle."

A23

It is Coming!

What? The perfect motor bicycle — the machine that overcomes all the objections to motor cycling and includes all the comforts — the 5 h.p.

RALEIGH

FLAT TWIN MOTOR CYCLE

It is no ordinary motor bicycle, but something very special, full of new ideas, things which will set all the motor cycling world talking. The new Raleigh is worth waiting for.

RALEIGH CYCLE CO., Ltd., NOTTINGHAM

DIAMOND MOTORS.

THE RELIABLE MACHINES.

We are now commencing the manufacture of the following models:

- 2½ h.p. two-stroke, single-speed machine (Villiers engine).
- 2½ h.p. two-stroke, two-speed machine (Villiers engine).
- 2½ h.p. four-stroke, two-speed machine (J.A.P. engine. Enfield gear).

Book your order now for early delivery

THE D. F. & M. ENGINEERING CO., LTD.
VANE STREET, WOLVERHAMPTON.

Telegrams: Diamond. Telephone: 651. A.B.C. Code, 5th Edition, used.

SOLE DISTRIBUTING AGENTS:

London—Messrs. Robertsons, 157B, Great Portland St., London, W.1
Birmingham—The Stevens Cycle Co., Gooch Street, Birmingham.
Sheffield—Mr. E. W. Hatfield, 147, Norfolk Street, Sheffield.
Northumberland and Durham—Messrs. Travers, Ltd., Pilgrim Street, Newcastle-on-Tyne.

Well-known Motor Cycle Company is desirous of placing large contracts, for the manufacture of Engines and Gear Boxes, in the hands of a substantial firm capable of dealing with this work in bulk, and turning out a really sound Engineering job.

Firms interested should first address Box L9323, "The Motor Cycle."

The Critic in the Saddle.—

cost me a broken frame, due perhaps to the curved top tube. Needless to say, the sidecar became out of favour. The twin James, I consider, is, in the main, one of the finest solo machines made.

Sidecar or Solo Mounts.

Becoming tired of running off without being accompanied by my wife, I reluctantly parted with my favourite and took over a 5-6 h.p. A.J.S. combination with accumulator lighting. I had access to a charging plant, and therefore this system was worth while. Comments on this machine in general are bracketed with those on my later machine of the same make. Suffice it to say that, as a touring outfit with 700 x 80 mm. tyres in South Africa, this machine comes nearest to present-day requirements, though for prevailing road conditions a well-designed spring frame would be an asset.

Passing now to English climatic and road conditions again, my next acquisition was a step in another direction, viz., a 3½ h.p. single-cylinder Rover, semi-T.T. bars, and chain-cum-belt transmission.

The *ensemble* in this case is excellent, and detail design very well carried out, necessarily making the machine on the heavy side. The front forks were improved as regards comfort by the fitting of Terry's links, although I think the principle of making these springs take both tension and compression is bad. The aluminium chain case is a very commendable feature, as is also the silent-chain drive. The multiple plate cork inset clutch was found to be the most satisfactory of any type yet used, and was extremely sweet in action. It was found to be advantageous with this machine in hilly country, especially with a sidecar, to pack the cylinder base up $\frac{3}{16}$ in. With the approach of winter it was decided to part with the Rover in favour of a more powerful combination, and a standard 1915 A.J.S. outfit was obtained, which after a little tuning and a few replacements turned out to be a powerful outfit. I fitted this machine with 700 x 80 mm. tyres, which together with the very heavy Brampton type forks gave extra riding comfort on the rough stretches.

The Large Type Twins.

I consider that the A.J.S. 6 h.p. engine is the most successful attempt for its size yet made for sidecar purposes. The moderate compression, large valves, and light pistons go largely to confirm my views. It is probable that the power and efficiency could be further increased by fitting a larger exhaust system, especially in the piping. Many makers of the larger types of twin engines do not pay enough attention to the cleanness of design in exhaust pipe and tail pipe shapes, and as a consequence it is often difficult to clean these thoroughly. If the A.J.S. fitted heavier gauge chain cases, I believe it would become even more popular than it is at present. After all, it is not difficult to design a satisfactory oil bath chain case, clean and reasonably simple in construction.

A word or two will not be out of place on what is becoming a rather worn subject, viz., the kick starter. Personally my experience with this device in general has been a very happy one on later machines. Perhaps it might be said that all these machines are of good repute; nevertheless, my contention is that

far less adverse criticism would be offered if riders would keep the detail adjustment of their power plants in better order. It is futile to blame the kick starter if one does not take the trouble to keep contact breaker points and plug points in good order and proper adjustment; eliminate air leakage in inlet valve stems and induction pipes (no insulating tape should be used in a sound engineering job) to keep the carburetter in correct adjustment according to the atmospheric conditions prevailing at the time, and several other seemingly paltry, but equally important, things should be kept in mind.

Suggestions to Manufacturers.

The following suggestions are offered for the consideration of designers and manufacturers when drawing up detail specifications of machines such as will be wanted by the public in future.

In most cases the diameter of the crank pin might be increased with advantage, and in some engines the diameter of the gudgeon pin also. Shafts in which Woodruff or other type sunk keys are used might also be increased in diameter, so as to minimise the tendency for such keys to turn over under repeated impact loads.

Oil should certainly be led under pressure primarily to the big end bearing, unless, of course, roller bearings are adopted.

Pistons should undergo suitable normalising heat treatment before finish-machining or grinding is carried out to release initial local casting stresses, which are often the unsuspected cause of much loss of power in engines, especially if an over-zealous speedmonger commits the unpardonable mistake of overrunning his engine during the first 400-500 miles.

General Layout Proposals.

The opinion is offered that it would be better from many standpoints to reverse the usual order of general layout regarding transmission and position of timing gear, and place both drive from engine to the gear box, and from the latter to back wheel, together with magneto contact breaker, on the right-hand side of the machine, and the timing-gear on the left-hand side. Chain troubles occur much more frequently than do valve troubles, besides which it would be much easier to get at the valves and tappets in the suggested position than is the case at present with the chains when cases have to be removed from amid sidecar connections and framework.

It should be insisted that the magneto be placed well up and behind the engine on a firm baseplate, and not on a sort of improvised platform as has been seen on many well-known makes recently. The New Hudson arrangement is to be commended.

Ball bearings in wheel hubs should be of ample size, and adjustment should certainly be provided on the outer races and not on the spindle races.

Footboard supports in many cases are not nearly stiff enough, and usually develop a certain drooping tendency, maybe spoiling an end view, which, otherwise, would be quite pleasing in appearance.

Lastly, as most readers of *The Motor Cycle* have a certain fund of commonsense, no further words need be wasted in endeavouring to further the already very live agitation in regard to the universal adoption of the spring frame for all types of machines.

SPECIAL FEATURES

REPORTING THE T.T. BY AEROPLANE.

BRAKES

MOTOR CYCLE HORNS AND SIRENS.

TIME TO LIGHT LAMPS
GREENWICH TIME.

Feb. 20th	...	5.51 p.m.
" 22nd	...	5.55 "
" 24th	...	5.58 "

Italian Regulations.

The ration of petrol to motor cyclists in Italy is now seven gallons a month. The importation of foreign machines is prohibited except by permit.

The New A.J.S.

The makers of the A.J.S. have gone back to detachable heads in the 1919 model. It may be remembered the military model did not embody this feature.

Carburettors.

Carburettor manufacturers are settling down to motor cycle models again. The carburettor of a lightweight motor cycle appears to be ridiculously small after handling aeroplane instruments almost as large as two-stroke engines.

Standard Benzole.

The National Benzole Association have fixed a standard for benzole to be used as motor spirit. It will be free from acids, alkalies, and sulphur, like water in appearance (pre-war benzole generally had a yellow tinge), and the specific gravity will be .870 to .885.

Appeal to London Motorists.

The Hospital Motor Squadron, attached to the R.A.C., appeals for transport for the wounded still in London hospitals to the various entertainments provided for them. The commandant is Mr. A. J. Wilson, of 154, Clerkenwell Road, London, E.C.1.

Second-hand Prices.

The following is a selection of average prices asked for second-hand machines, as advertised in *The Motor Cycle* for February 6th and 13th. It will be noticed that there is a slight advance on the previous averages published.

	Previous 1914	1916 to and 1918	
	1914.	1915.	1917.
A.J.S., 6 h.p., and sidecar	—	£82	£93
Allon, 2½ h.p., 2-stroke	—	£35	£42
B.S.A., 4½ h.p., and sidecar	—	—	£73
Douglas, 2½ h.p.	£35	£41	£57
Enfield, 3 h.p.	—	£41	£51
Enfield, 6 h.p., and sidecar	—	£67	£94
H.-Davidson, 7-9 h.p., sidecar	—	£74	£111
Indian, 7-9 h.p.	—	£43	—
Indian 7-9 h.p., and sidecar	—	£76	£110
Rover, 3½ h.p.	£22	£42	£80
Rudge, 3½ h.p.	—	£34	—
Sunbeam, 3½ h.p.	—	—	£83
Triumph, 4 h.p.	—	£43	—
Triumph, 3½ h.p.	£27	—	—
Zenith, 7-9 h.p., and sidecar	—	£70	—
Zenith, 4-5 h.p., and sidecar	—	£51	—

Freaks.

Although war time experience has resulted in several new cars which can be regarded as freaks, nothing of this nature has been produced by the motor cycle industry so far.

"Motor Cycles and How to Manage Them."

For some months past, owing to the absence of printing work's staff on service, the handbook "Motor Cycles and How to Manage Them"—has been out of print, but we are now pleased to announce that a new edition (the nineteenth) is now ready, and copies are obtainable from the publishers. Iliffe and Sons Ltd., 20, Tudor Street, London, E.C.4, price 2s. 6d. net, by post 2s. 10d.

Petrol Prices.

The maximum wholesale prices of petrol are set forth in a new Order issued by the Board of Trade last week, and are as follows:

	Per gal.
	s. d.
Aviation spirit (in 2-gal. cans)	3 0½
Special boiling points (in 2-gal. cans)	2 11½
No. 1 grade (in 2-gal. cans)	2 10½
No. 2 " " "	2 9½
No. 3 " " "	2 8½

In Scotland and Ireland, 1d. per gallon may be added to all the above prices. The retail prices are represented by the addition of 5d. per gallon in each case.

An American T.T. Race.

We learn that there is some talk in American motor cycling circles of establishing an event similar to the T.T. Race. The general feeling in America is for a closed event for stock machines, and the suggestion has been put forward that in 1920 the winners of the British and American events should compete against one another. In our opinion, however, it is extremely doubtful whether a T.T. race will be held this year.

Institution of Automobile Engineers.

Two meetings have been arranged in Birmingham which will form part of the regular Session of the Institution of Automobile Engineers, though both the papers to be read will deal specifically with points connected with the design of motor cycles.

The first paper to be read at the Birmingham Chamber of Commerce to-day, February 20th, by Mr. D. S. Heather, B.Sc., will be entitled "A Survey of Current Motor Cycle Design," and Mr. Heather will write as a rider rather than a designer of motor cycles.

The second paper will be read on Thursday, March 20th, at the same place and time by Mr. Eric Caudwell.

The address of the secretary of the Institution of Automobile Engineers, from whom tickets of invitation to both these meetings may be obtained, is 28, Victoria Street, Westminster.

An Indian sidecar outfit used by an American dealer for hauling motor cycles from the Hendee factory to his stores.

Fuel.

Almost every week brings forth some new concession from the Government concerning fuel supplies. It is not unreasonable to expect that shortly all restrictions may be removed.

Canadian Show.

Montreal is to have a motor show in April, the profits from which will go to aid the Montreal Soldiers' Wives' League. A number of motor cycle exhibits will be included.

Petrol Vouchers.

The Board of Trade announces that the vouchers of motor spirit licences issued by the Petrol Control Department may now be used for obtaining supplies during any month. The months printed upon the vouchers may be ignored.

How to Fly.

Those motor cyclists who read and enjoyed the articles which appeared in *The Motor Cycle* during 1918, entitled "Flying Facts and Theories," by Capt. W. G. Aston, R.A.F., A.F.Ae.S., A.M.I.A.E., will be rejoiced to learn that a book on the elementary principles of flying by the same author has recently been published.* We cannot indicate the objects of this book better than by a couple of quotations from the introduction. "The primary function of this book is not to teach you why aeroplanes fly, for that is the province of the abstruse physicist, but to try and explain how they fly. And again—"I give it as my honest and considered opinion that more people have been killed while flying because they have been incorrectly or inadequately informed of the principles of this science than through any fault of the structure of the aeroplane."

The subject is dealt with in quite a simple manner, commencing with the necessity for a streamline form and the movements of the air, following which we find much information respecting the angle of attack and the shape of the wings. The construction of aeroplanes is described and illustrated by an immense number of drawings.

* "Aeronautics Made Easy." Published by Messrs. Illife and Sons Ltd., 20, Tudor Street, London, E.C.4. Price 4s. 6d. nett, by post 4s. 10d.

A Spanish cycle car, the Edis, which has an 8-10 h.p. two-cylinder engine, 83.5 and 100 mm. bore and stroke respectively. The transmission is by shaft and lin. V belts, while the suspension is by quarter elliptic springs. The weight is approximately 5 cwt.

THE DISPOSAL OF ARMY MOTOR CYCLES.

It is probable that three methods will be employed in disposing of the Army motor cycles. In the first place, the Surplus Government Property Disposal Board may sell them in blocks; it may sell vehicles of an old pattern, or those which may be described as of a non-standard type, by auction; and, lastly, the Board may permit manufacturers to take a certain number of their own vehicles on conditions which would probably represent a compromise upon the original proposal to this effect put forward many months ago.

It seems, however, that at the present moment no definite decision has been reached, and the foregoing suggestions are, therefore, purely of a speculative nature.

We stated last week that Lt.-Col. C. V. Holbrook is Controller-in-Charge of the Mechanical Section of the Surplus Government Property Disposal Board. Among the advisory committee appointed to aid him are Mr. H. C. B. Underdown (Chairman of the A.B.M.A.M.), Mr. Julian Orde (Secretary of the R.A.C.), and Mr. F. Strickland (a well-known consulting engineer and writer).

Rear Lights.

There is no present prospect of the rear light regulation being rescinded in the case of cycles or motor cycles.

The Clyno Two-stroke.

Although it had been decided to abandon the manufacture of the Clyno two-speed two-stroke, in order to concentrate upon the 8 h.p. model, the Clyno Engineering Co. have decided to market this little machine this year. Several improvements will be embodied, including 24in. tyres instead of 2in., handle-bar control to magneto, hand-controlled clutch, increased number of clutch plates, belt guard, wider guards, Brampton forks, and drip feed lubrication instead of petrol. The price will be about £50, and deliveries will commence about Easter.

The Automobile Association and Petrol Licences.

To expedite the issue of petrol licences to motorists, the Petrol Control Department has specially authorised the Automobile Association to receive applications for fuel allowances, accompanied by crossed cheques, made payable to H.M. Paymaster-General, (not to the A.A. and M.U.), to cover the amount due for the duty of 6d. per gallon.

The Automobile Association hopes to be able to post petrol licences to applicants on the day following the arrival of applications and cheques at the head offices, A.A. and M.U., Fannum House, Whitcomb Street, London, W.C.2.

"A SURVEY AND CURRENT MOTOR CYCLE DESIGN."

THE inauguration of a motor cycle section of the Institution of Automobile Engineers is a matter the importance of which cannot be over-estimated at the present time. It means the bringing together of the motor cycle engineers and designers for their mutual benefit through an interchange of ideas and criticism.

Entitled as above, the paper to be read at Birmingham this evening by Mr. D. S. Heather, B.Sc., marks the commencement of this new era, and is decidedly appropriate for the occasion, being a criticism of general modern motor cycle design as a whole. Every detail of construction is dealt with in a thorough manner, and indicates clearly the direction in which progress in design should be directed.

Among the shortcomings of present-day engines. Mr. Heather instances

the unsatisfactory features of built-up crankshafts in conjunction with inside flywheels, and the restricting effects of this on other details, such as roller big ends, and the trouble in dismantling.

Beside the inherent drawbacks of the internal flywheels there is also to be considered their effects when the splash system of lubrication is adopted. Piston distortion and gudgeon pin fixing are thoroughly dealt with, and remedies for their failings suggested. The most unsatisfactory feature of engines appears to be that everything is cramped and restricted as to size, particularly such members as timing mechanism, tappets, and bearings generally. Sufficient clearances are not allowed in such places as magneto, gear cases, etc. Bearings are consequently shortlived, noise early develops, and oil is exuded on to the outside of the machine.

Mr. Heather's suggestions then, are for solid crankshaft, outside flywheel, and some system of forced lubrication, with the gudgeon working in bearings in the piston. A further section of the paper deals with the comparative merits of the various types of engines at present used on motor cycles; the small two-stroke, the horizontal twin, the single, and V twins of varying angles.

Other sections of the paper deal with clutches, gear boxes, transmissions, frames, rear springing, front forks, and miscellaneous details.

This paper, though offering many good suggestions, is, on the whole, intended to be somewhat of a destructive criticism, and has been written to a certain extent in conjunction with a constructive paper on practically the same subject, to be read at next month's meeting by Mr. E. Caudwell.

**Eastern Counties M.C.**

Particulars of membership of this club may be obtained from the hon. secretary, Mr. J. W. Percival, 5, Ruby Road, Walthamstow. Professional competition riders are not eligible as members.

Carlyle M.C.C.

The committee of the Carlyle M.C.C. held a meeting on the 12th inst., when a sub-committee was appointed to arrange a sporting and social programme, particulars of which will be published as soon as possible.

Old friends and intending new members are invited to communicate with the secretary, Mr. T. Laffeaty, 7, Vale Terrace, King's Road, Chelsea.

Darlington B. and M.C.

At the special general meeting of the Motor Section of this club, held on February 10th, it was decided to re-form the club.

The opening run was fixed for April 18th, at Bylands Abbey, where lunch will be provided.

Motorists wishing to join the club should communicate with the honorary secretary, Mr. T. W. Watson, Central Chambers, Darlington.

Ealing and District M.C.C.

In conjunction with the A.C.U. this club is endeavouring to arrange the standardisation of a motor cycle team for all clubs, so that, in inter-club events, fixed teams will compete.

Sporting trials both for experts and beginners will be held, and social events and smoking concerts, etc., arranged in conjunction. It is proposed to arrange for country headquarters about twenty-five miles from London, on a main road, so that members can obtain hotel accommodation and meet other members whilst on the road. The opening run will take place in March or earlier, date to be published later.

Woolwich, Plumstead, and District M.C.

The general meeting was held on February 10th, and was well attended. A resolution was passed challenging any motor club in the kingdom to provide a team to compete with them for the Woolwich club's inter-team challenge cup, the course to be 50 miles and a non-stop on Kentish roads. Full particulars of this event may be had on communicating with the honorary secretary, Mr. F. J. Ellis, 3, Nightingale Place, Woolwich, S.E.18.

The next general meeting takes place at 8 p.m. on February 24th. It has been decided to hold the opening run on March 2nd to "Three Horse Shoes," Knockholt.

Aug. 2 and 4.—Dublin M.C.C. Two Days' Reliability Trial.

Sutton Coldfield and Mid-Warwickshire A.C.

The Imperial Hotel, Temple Street, Birmingham, is to be the venue of the A.G.M. fixed for the 21st inst., at 7 p.m. The secretary is Mr. F. W. Finne-more, A.C.A., 122, Colmore Row, Birmingham.

Liverpool M.C.

At the crowded meeting held on the 5th instant, fifty-seven members were enrolled. The officials were elected, including the secretary, Mr. V. E. Horsman. A number of events were decided upon—among them the opening run to Llangollen at Easter.

We shall be pleased to hear again from secretaries and others regarding existing and proposed clubs, their programmes, and any other interesting particulars. We are also prepared to assist with advice or publicity those desirous of establishing clubs in their own localities.

Essex M.C.

As notified previously, the annual general meeting of the above club will be held on March 4th at the R.A.C., Pall Mall, S.W., at 7.45 p.m. All those interested are invited to attend. Nominations and notices for agenda must be in the hands of the honorary secretary not later than the 25th inst.

Auto Cycle Union.

It may be remembered that it was decided to run off the Arbuthnot Trophy as early as possible after the cessation of hostilities. This competition is open to Naval officers at present serving in H.M. Navy. The A.C.U. is now engaged upon drawing up the rules and regulations, and Maj. A. M. Low, R.A.F., and Mr. E. M. P. Boileau, have been appointed to proceed to Portsmouth to discuss details with the officials of the Naval M.C., whose co-operation is sought.

The competition will be in the nature of a reliability trial, and the winner will be found among survivors after a subsequent hill-climb or speed test.

The Competitions Committee of the A.C.U. recommend that the Six Days' Trial be held in August or early in September, in South or Mid-Wales, and a suitable centre is being sought.

Special attention will be paid towards the encouragement of lightweight motor cycles of the cheaper kind.

The difficulty in getting out a handbook has been found to be almost insurmountable, but it is hoped to publish a supplement to the list, which will give latest information.

A travelling representative has been appointed for inspection of hotels and repairers' garages. A large number of applications for appointment have been received from hotels and garages.

Nothing definite has been decided regarding the T.T. Reports have been received from the Island, one of which states that the course is in such a bad condition that the race could not possibly be held, while other reports state that the condition of the roads is not so bad as has been stated, and that they can be easily repaired. In the meantime, news from the various manufacturing firms, as to whether or not they would support the T.T. race this year, is awaited. Among certain firms it is felt that the running of this race would impose too heavy a task upon the trade, in view of its unsettled state owing to the changing over from war to peace conditions, and that, while the T.T. race will be heartily welcomed in 1920, it would be most inconvenient to the trade generally to run it during the present year.

THE 2 $\frac{3}{4}$ h.p. COULSON-B.

71 mm. x 88 mm. Single-cylinder Blackburne Engine, 348 c.c.

The 2 $\frac{3}{4}$ h.p. Coulson, a newcomer into the motor cycle industry. It is fitted with a spring frame and Blackburne engine.

WE recently published a few preliminary details concerning the 2 $\frac{3}{4}$ h.p. Coulson-B motor bicycle. The machine has now reached an advanced stage of construction, and in about three weeks' time the manufacturers, the Aeroparts Manufacturing Company, Albion Works, Albion Street, King's Cross, London, N.I., hope to be in a position to make deliveries.

The machine has a simple spring suspension. The frame is sturdily constructed of 1 $\frac{1}{2}$ in. tubing. On the under side of each chain stay there is a leaf spring, the rear end of which is attached by means of a shackle to a link carried at the end of the back forks.

Both front and rear wheel spindles are withdrawable, so that either wheel

may be instantly detached for the purpose of tyre repairing.

As previously mentioned, the mudguards are wide and generously valanced, the rear guard being 5 in. across. Between one and three-quarters and two gallons of petrol and a quart of lubricating oil can be carried in the tank, which is fitted with filler caps of large size at the forward end. The tank is attached to the secondary frame tube by means of special brackets, the method of attachment being invisible on casual inspection.

The engine is the 2 $\frac{3}{4}$ h.p. Blackburne, which is a small replica of the well-known 3 $\frac{1}{2}$ h.p. engine of this make, and, like the latter, is provided with an outside fly-wheel. The standard Blackburne features are retained, such as the detachable head,

solid crankshaft, and split big end bearing. The bore and stroke of this engine are 71 mm. and 88 mm. respectively (348 c.c.). The engine equipment includes the latest type Brown and Barlow pilot jet carburetter, M-L magneto, and a streamline silencer.

The stand is fitted just behind the bottom bracket on which the countershaft Albion two-speed gear box is suspended. The handle-bars are of the semi-T.T. pattern, and are provided with rubber grips and inverted levers for the front brake and exhaust lifter. The forks are Druid stronger type Mark II., and cast aluminium footboards with a rubber rest for the heels are provided. The total weight of the machine is estimated at between 150 and 160 lb.

A Grado Pulley with Kick-starter.

JUDGING from the number of single gear machines in existence and the demand for change speed gears, the variable gear device illustrated here will be welcomed by a large number of riders who are now fitting up second-hand machines. It is a Grado expanding pulley, giving a free engine and ratios from 4 to 1 to 8 to 1, and embodies a kick starting gear.

The principle of the Grado pulley is known to many of our readers. The outer flange continuously tends to close in on to the inner flange, thus gripping the belt in whichever position it may be. In fact, if the controlling mechanism is freed, the pulley will gradually close and raise the gear, unlike the majority of similar gears, which always incline to open out.

The Grado Co. has now embodied a kick-starter, which is quite simple in construction. A gear wheel is carried on

The ratchet gear wheel and kick-starter segment.

the pulley, and is connected to the engine-shaft through a free-wheel ratchet arrangement. Behind this is a segment embodying a pedal lever, which, upon being pressed down, engages the segment with the free-wheel pinion and turns the engine.

The segment is carried on a bracket supported by the operating mechanism of the pulley, and is stayed by a long diagonal rod in tension. The whole of the kick-start device moves laterally with the outer pulley flange, but provision is made to prevent any stress being imparted to the engine-shaft. This latest design also has an improved method of attachment to the crank case, which permits it being fitted to almost any engine without undue trouble. The price of this model is £9 9s., and the makers, Messrs. Grado, Ltd., Pershore Street, Birmingham, hope to commence deliveries during the next three weeks.

THE NEW 8 h.p. CLYNO.

A Modern Machine designed throughout from the Point of View of Overseas Riders.

The 8 h.p. peace model Clyno. 76 mm. bore, 102 mm. stroke; 925 c.c. capacity; detachable heads; 28in. x 3in. detachable wheels; mechanical lubrication; spring frame.

WE have long urged that British motor cycle manufacturers would benefit by more careful attention to the insistent demands from Overseas for a machine in every way suitable for the special requirements which were only fully covered in the big twin class by certain American machines.

What is required by a large number of Overseas-buyers is a large capacity engine, 28x3in. tyres, spring frame, and, coupled with such a specification, British quality in design, material, and workmanship.

The Clyno Engineering Co. in their "peace model" have, it will be seen, appreciated the needs of a vast proportion of the Overseas market, for the new Clyno has been designed

throughout, from the point of view of the Colonial, and the result is a machine which sets a new standard of design which will be appreciated just as much by riders at home. The popularity of American machines in this country and Overseas indicates that what is absolutely essential in the Colonies is also desirable in Great Britain; hence, while the motor cycle designed for this country may not be suitable for South Africa or Australasia, the true Overseas mount is equally good for home or abroad.

The general outlines of the new Clyno, at first sight, appear to follow those of well-known American machines. This, however, probably is due to the high ground clearance (over six inches), the spring frame, and unconventional looking carrier; because, upon examination, the general design is more British than American.

The Spring Frame.

The frame is of very substantial construction, the makers' experience with their machine gun sidecars being responsible for several special features, notably the exceptionally strong head, which has massive, but by no means ugly, webs, on each side and at the rear of the casting. Both top tubes slope towards the rear, terminating in a single member embodying the carriers for the rear springs, and a lug for a vertical tube, which takes the place of the more conventional "seat" tube. The foot of this tube is the pivoting point of the rear wheel frame, between which and the engine the gear box is carried. Forward of the latter unit is another "down" tube, the only bent tube in the principal frame structure. This supports the engine on one side and the gear box lugs are integral with the frame, the

two rear members being on the vertical rear tube, while, to meet the stresses caused by the sidecar, the front down tube is 1½ in. in diameter, and strengthened internally by high tensile steel tie-bars.

Comparatively short springs with seven leaves are hinged at their rear ends on the sides of a loop member over the wheel, which in turn is pivoted at the ends of the chain stays. The bearings of the loop are of good size, while at the frame end the bearings carrying the stays are calculated to prevent any lateral play. All moving parts are equipped with grease cups. The carrier is on the spring portion of the machine, and is of tubular construction.

Mudguards and Wheels.

Deep valances are fitted to the 5in. rear mudguard, which is well stayed, as is the wide front guard.

Quickly detachable and interchangeable 28in. x 3in. wheels with voiturette rims are fitted, and these have solid steel hubs and large adjustable ball bearings.

Gear unit, showing the combined magneto-dynamo, which may be fitted to order.

The rear springing of the new Clyno.

The New 8 h.p. Clyno.—

An 8in. internal expanding brake is fitted on the driving mechanism at the rear wheel, and is operated by a pedal on the left side of the machine. The shoes are faced with Ferodo, and therefore renewable. The front brake is of the conventional type, i.e., fibre pads in shoes working upon the rim of the wheel and operated by lever on the handle-bar. The latter is of good width, gives a comfortable riding position, and in shape may be described as a step between the conventional upturned bar and that which is known as "semi-T.T."

Front and back stands and Brampton type forks complete the main elements of the frame.

The Long-stroke Engine.

We may say that it is a long time since we were so favourably impressed by a motor cycle engine, both in the points of design and performance. The bore and stroke are 76 and 102 mm. respectively, which give a total capacity of 925.5 c.c. The cylinders are set at 42°, which we think is somewhat unique in British machines, the most general setting being 50°. The cylinder dimensions show that the engine is of the long stroke type; in fact, the stroke, in proportion to the bore, is longer than that of any British twin motor cycle engine hitherto produced, the ratio being nearly 4 to 3.

Important features are the detachable heads and the methods adopted to hold them in position. On two sides of each cylinder there is a swivelling bolt extending from the crank case to above the cylinder heads where they are linked by bridge members, which bear upon the centre of the cylinder heads. The part in contact is concave on the cylinder and

Strong metal chain cases are fitted which are readily detachable.

convex on the bridge piece, which makes the latter more or less self-centring.

To detach a cylinder head it is only necessary to remove one nut, slacken the other, and swing the bridge piece clear. The head removed, together with the valve chests and valves, the cylinder barrels may then be withdrawn without further use of tools.

The cylinder barrel is spigoted into the head, and a gastight joint made by the usual copper and asbestos ring. The top fin on the cylinder barrel is "dished" to receive the rim of the socket portion of the joint.

Thirteen fins encircle the cylinder barrel and are joined together at four points of the circumference by what may be described as vertical webs. The head portion has "upright fins" across it, while the valve chambers have fins arranged approximately radially.

The pistons have flat tops, and are of cast iron, with four webs. Three rings are fitted at the top, and below them for nearly half its total length the piston is recessed, and has a narrow skirt with a strengthening rib about its bottom edge. In the waist of the piston are a number of holes, introduced to

The 8 h.p. Clyno engine. (Left) The valve-operating mechanism. (Centre) Cross-section of the engine showing the bearings. Note the small lubricating pump on the timing side end of the main shaft, and the oil trough about the base of the cylinder. (Right) Section through the engine, showing the small ends of the connecting rods and the roller "big end."

The New 8 h.p. Clyno.—

lighten it. Extra long bosses are provided for the gudgeon which works in them. The gudgeon pin is fixed in the small end by means of a cross bolt, the connecting rod having a saw cut from the lower part of the small end bore extending into the I section rod, to allow the small end to grip the gudgeon pin when the bolt is tightened up. Thus, it is evident that, instead of the connecting rod working upon a fixed gudgeon pin, the latter moves in the bosses in the piston. By these means there is approximately a hundred per cent. gain in bearing surface over the more conventional bushed small end.

The "Big Ends."

As will be seen from the drawings, one connecting rod is forked, which is another departure from previous Clyno practice, the 5-6 h.p. model having side-by-side connecting rods. The big ends are fitted with roller bearings, each having two rows of rollers in bronze cages. The plain connecting rod has two rows side-by-side, while the forked rod has a row on each side of the other pair. The cages are of one type, and the pair on one side faces the pair on the other, having a hardened and ground steel ring between them. The big ends are lined with renewable hardened and ground steel rings.

Crank Pin.

The method of fixing the crank pin is novel. Although it has been in use some time on war-time Clynos, the design is not generally known by the motor cycling public. The crank pin is hollow, and has tapered ends, which fit in tapered holes in the flywheels. Through the centre of the pin there is a shouldered bolt, with a large head on one side and a shouldered nut on the other. By tightening the latter, the crank pin is pressed firmly into the flywheels. Each

The gear box and magneto are fixed by wedging clamps, thus preventing any possibility of misalignment.

end of the bolt has a locking device, which will be seen in the third drawing of the engine.

Main Bearings.

Long plain phosphor bronze bearings support the main shafts, the adoption of which, no doubt, contributes to the silence of the engine, which we inspected after many thousands of miles of running.

A single cam wheel, which is supported in bearings at both ends of its shaft, operates the valves on both cylinders through three pairs of rockers. The exhaust rockers, having the greatest

amount of work to do (i.e., to open the exhaust valves against the pressure of the expanding gas in the cylinders), are fitted with rollers. Two pairs of rockers are used to operate the inlet tappets, the arrangement of which will be clear from the drawings.

An extremely neat exhaust valve-lifting mechanism is embodied within the timing gear case. This is in the form of a stirrup which, upon being raised by means of a Bowden wire, takes both exhaust rockers out of action. Means of adjustment are provided by two knurled collars.

The tappets, which are adjustable, are equipped with light springs to keep them in contact with the valve stems, while double springs are fitted to the valves, which are of ample diameter.

It will be seen from the drawings that the induction pipe is very short, and is fixed by screwed collars, which compress washers of asbestos, and so obviate all chance of air leaks at this important point.

Exceptionally large exhaust exits are provided, with 1½ in. exhaust pipes carrying the spent gases in easy curves to a long 4½ in. barrel silencer.

Lubrication.

At their lower ends the cylinders extend deeply into the crank case, the space between them and the crank case walls being utilised as an oil trough into which fresh oil is pumped by a small eccentric pump on the engine-shaft. This pump draws its supply of oil from a drip feed on the tank. In the walls of the cylinder barrels are a number of holes through which the oil overflows and so lubricates the pistons. In addition to these holes, there is a pipe in the trough through which oil flows directly to the timing side main bearing.

On the driving side the oil which drips down the inside of the crank case is collected in a trough just above the bearing, to which it is fed by a large oilway.

No special means are adopted to lubricate the crank pin and gudgeon pins, which secure their share of lubricant by splash in the usual way. In addition to the mechanical lubrication system, the machine has an auxiliary hand pump with a two-way tap, by which the driver may give either engine or gear box a charge if and when required.

Shock Absorbing Device.

In our previous reference to the new Clyno on the road we mentioned the extremely smooth running of the machine. There is no doubt that the shock absorber largely contributes to this. The device consists of a sprocket, free on the engine-shaft, and having four cams on its outer side. These bear upon four spring-loaded plungers carried in a member which is fixed to the engine-shaft. Thus, the impulse of the engine does not impart a shock upon the transmission. In addition to the spring pressure, there is the frictional contact between the sprocket and the member against which it is held by the plungers.

The Gear Unit.

We are not permitted to give full details of the new three-speed gear box. It is interesting to note, however, that,

while the gears are the same size as the gear unit of the 5-6 h.p. model, the complete box is 6 lb. less in weight. The layshaft is of the built-up type, while the gear wheels are ½ in. and ¾ in. wide. All gears are in mesh, and engagement is obtained by dog clutches of the internal tooth type. The kick-starter is entirely enclosed.

The clutch is of the multiple plate type, with cork inserts, and fitted with roller bearings. It embodies a single adjusting spring, and is operated by the right foot. On the top of the gear box is carried the magneto or mag-dynamo, whichever may be fitted. This is driven by a chain enclosed in an aluminium case as hitherto.

At every point it has been remembered that it is necessary to guard against sand clogging the working parts, which are usually exposed. For example, the quick thread operating the clutch, although only outside the case for less than ¼ in., is protected by a sleeve.

Built up Chain Cases.

The ½ in. x ¾ in. chains are entirely enclosed in strong metal cases, reinforced and built up on castings, and are as solid as the aluminium type previously fitted. The method of construction has been

On the big end bearings each connecting rod takes two cages of rollers. Note the central dividing washer.

thoroughly tried out on the sidecar machine guns supplied to the Government. The mode of fixing is simple, and renders their removal an easy matter.

Accessibility at every point is a strong feature of the design. The footboards and pedals are built up as a complete unit, which may be removed by withdrawal of two bolts. The clutch is rendered accessible by detaching two screws on the domed cap and two nuts on the top of the case.

Space does not permit of a detailed description of the sidecar, which we leave for a later date. It suffices to say that it is a carefully thought out design, embodying a wheel sprung by quarter-elliptic leaf suspension.

The body is roomy, and is suspended on large C springs.

Altogether the new Clyno impresses us as a thoroughly sound proposition, and one which will remove much of the complaint against the British motor industry, that Empire trade is not regarded seriously.

Springing and Frame Design.

A Pressed Steel Construction having many Good Features.

MR. P. A. Fisker, of Copenhagen, has undoubtedly gone a long way towards achieving the embodiment of the ideas of super-refinement enthusiasts in his patented motor cycle design here illustrated.

The principal features of the construction are the duplex pressed steel members carrying the engine and connecting the steering head and the rear wheel stays. The saddle is supported by the steel tank, which is attached to the steering head at one end, and the main frame

plates at the other. The springing is of a decidedly novel type, comprising long lever arms and helical springs. The extra saddle, which is fitted in place of the more usual carrier, is also sprung. A great deal of attention has been paid to mudguarding. The pressed members are stiffened laterally by wide footplates extending the whole length of the engine. The engine rests on another plate, which forms an undershield, so that it is practically enclosed in a mudproof cradle.

A four-cylinder engine is shown fitted with a simple type of totally-enclosed shaft and bevel drive.

No indication is given in the specification of any further provision of means for the prevention of lateral play in the springing of either wheel. Failing any additional support, to that shown at these points, we should expect the side movement to be considerable.

The frame construction, however, as a principle, has much to recommend it.

A unique Continental design.

THE MOTOR CYCLE ON ACTIVE SERVICE AND AFTER.

MOST of our pre-war readers will remember W. B. Little, whose sensational exploits on Skiddaw and Helvellyn with a motor cycle caused him to be known as the "Motor Mountaineer." He was well-known, too, as a consistently successful competition rider, winning, among other prizes, the award for the best amateur solo performance in the 1912 A.C.U. Six Days.

At the time the war broke out, Little was in France as a competitor in the

Little joined the Army almost immediately, and in April, 1915, he was in France, a captain in the Durham Light Infantry, and served some time on the Brigade staff, later being second-in-command of the 5th Border Regiment. In 1917 he was given command of the same battalion. In March, 1918, this battalion had so many casualties that it was amalgamated with another Border battalion, and Little was given command of a Manchester battalion until it was disbanded. August last saw our friend in command of the 6th Royal Dublin Fusiliers, with which regiment he is now in France—a lieutenant-colonel.

Lt.-Col. Little has been awarded the D.S.O. and bar, and the M.C. He has been mentioned in despatches four times, and promoted brevet-major in the Regular Army.

Lt.-Col. Little writes that he has been out of touch with motor cycling matters during the past four and a half years, but is very optimistic concerning the future of the pastime.

"One thing is certain," he states, "motor cycles have more than upheld their own in this war. How the necessary communication between formations could have been kept without them I cannot imagine. During the warfare of movement they had even more to do than during stationary warfare, and to say 'they did it' is the least one can say of them. Once the Army is settled down again in civilian life, I forecast a phenomenal demand for motor cycles. In fact, this war has made this, more than ever, a mechanical era, and every man, according to his means, will want some mechanical method of locomotion. I hope the fuel supply is being dealt

with sufficiently far ahead to meet the demand. Doubtless *The Motor Cycle* will do its share in reviving the old clubs, competitions, T.T. races, etc. These must be got going again, even if it is only for the sport that there is to be got out of them. Naturally, many of the old school of riders will feel a little past active participation, at any rate judging from myself, but, nevertheless, there is the coming generation to consider."

DRIVING BOTH WHEELS OF A SIDECAR OUTFIT.

A SIDECAR outfit having both rear wheels driven is the subject of a patent taken out by Mr. W. F. J. Simpson, of Reigate, Surrey. The design is interesting because, despite its differential and apparent complication, it still retains the main elements of a sidecar, inasmuch as it can be detached from the motor cycle in order that the latter may be used as a solo machine.

That is its main feature; were it integral with the motor cycle frame, it would be but a hybrid runabout without the latter's advantages—i.e., protection for the driver from the elements.

The drawings reproduced are from the patent specification, but letters we have received from the designer state that he has more fully developed the idea, and probably will make a machine.

As will be seen from the drawings, both rear wheels are sprung, and, it is claimed, both wheels retain their relative position to each other by means of a link motion, thus avoiding strains on their respective frames.

The sidecar wheel is driven by an "axle" shaft, which is connected to the rear wheel of the cycle through a differential. The latter is carried in the hub of the motor cycle wheel, and, if the sidecar is detached, it may be locked up, thus permitting the machine to be used as a solo mount.

A patented sidecar chassis with driven wheel and differential.

Lt.-Col. W. B. Little, D.S.O., M.C.

International Six Days, which, it will be remembered, was abandoned at the outbreak of war. "The Motor Mountaineer" was forced to give up his machine, receiving in exchange a receipt from the British Consul at Lyons.

LETTERS TO

THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

THE THREE-JET BINKS CARBURETTER.

Sir,—Regarding the recent correspondence which has taken place in your columns *re* the Binks carburetter and controversy about "dead spot," we may say that of our half-dozen motor cycles the last two were fitted with the Binks carburetter, and this carburetter has always given us the greatest satisfaction, and we would sooner any day have a Binks carburetter plus a controversial "dead spot" than any other motor cycle carburetter on the market.

For the combination of easy starting, slow running, acceleration and economy, there is no carburetter that can touch it.
JAMES MONTEITH AND SONS.

RUSTLESS STEEL FOR MOTOR CYCLES.

Sir,—In your report of a paper read before the I.A.E. graduates at Coventry, it is stated that "this steel is of very good quality, approaching B.N.D."

It certainly is of good quality, but is a long way from B.N.D., at any rate as regards tensile. Stainless or rustless steel has an ultimate tensile of forty tons per square inch, whereas that of B.N.D. is about a hundred tons. Stainless steel would find its best use in exhaust valves, for which it has been very largely used in place of tungsten steel. It is easier to machine and nearly as good in regard to pitting, absence of deformation, etc., as the latter.

ERIC W. WALFORD.

OPINIONS.

Sir,—Having read the series of "Opinions" by men prominent in motor cycling, it seems to me that, though there are obvious advantages in concentrating on as few models as possible, there are so many different types desired by the public that, to cater for all, several models will have to be produced.

There is an evident desire for higher powered lightweights; yet the low-powered lightweight still requires advancement in order to see to what standard of efficiency the ultra-lightweight can be brought.

The comparative cheapness of the sidecar outfit lies in the fact that the motor cycle can be sold either for solo use or with the sidecar; but as few people ever detach the sidecar, except for getting at parts otherwise inaccessible, could not the same machine be sold, but with a different frame? Then the solo machine could be made with a frame suitable for solo use, and the sidecar made a permanent fixture; the same engine, gear box, transmission, and wheels being used in both cases. This form of manufacture might lead to the production of a cheap cycle car

or runabout, also a motor cycle by the same firm. If the cycle car were made within the same limits of weight as the average sidecar outfit, a 6 h.p. engine ought to be ample.

One firm one machine is becoming the motto at present; but could not firms producing different models combine together, and so lead towards interchangeability of parts amongst different models?
R.E.C.

Chatham.

LEAKAGE OF MAGNETISM.

Sir,—As an electrical engineer, and one who has had considerable experience in magnetos and automobile equipment, I have been very much interested in the controversy *re* the loss of magnetism in the Dixie magneto. To anyone who has studied elementary magnetism it is at once apparent that the magnetism in the Dixie must necessarily deteriorate, as the end of the shaft on which the driving sprocket is fixed is, to all intents and purposes, one pole-piece of the magnet. Consequently, the passing of the chain over the sprocket and on to the engine is a direct magnetic connection to the frame, and when travelling must set up a perfect magnetic touch. By "touch" I mean method of conveying magnetism from one point to another. Hence, as the frame of the machine absorbs the magnetism, the magnets of the magneto must become weaker.

The only cure I can suggest is the one that has already been mentioned, viz., fitting a gunmetal sprocket.

I notice "N.P.D." has done this, and remarks that a pin will still adhere to the teeth of the driving sprocket. If he still has the same driving chain on, this would cause the above effect, as the chain would retain its magnetism. If the effect is there without the chain, then I assume it must be a very small sprocket and the magnetism is purely of an inductive nature, which is by no means serious.

Regarding "F.C.C.'s" complaint of soft steel, he is perfectly correct in his assumption that permanent magnets must be of hard steel.

Whilst writing you, I would like to say that it is up to us motor cyclists to support home industry all we can, and particularly this section, as we can produce, and are producing at the present time, the finest examples of magnetos in the world, superior by far to any foreign product that ever flooded our market. This is a fact that I find requires some driving home; but I can assure all your readers that the usual standard of efficiency and reliability so synonymous with the word British is applicable to nothing so much as the present British magnetos.
SPARK.

Plan view of the new 8 h.p. peace model Clyno, an illustrated description of which is given on pages 184 to 186 of this issue.

MAGNETO DRIVE AND POSITION.

Sir,—I have read "Vedette's" article on "Magneto Drive and Position" in the January 30th issue of your very excellent paper with much interest.

I was rather surprised, however, to notice that, possibly inadvertently, no mention was made of the magneto transmission system employed on the Douglas.

I feel sure that many readers will agree that, in point of view of absolute freedom from dirt, extreme accessibility, simplicity of design, silent running, and general reliability, this type has much to recommend it.

I would, of course, add the usual disclaimer, being merely a very satisfied rider of this popular mount. 4 H.P.

Highgate, N.

Sir,—I notice that an eccentric drive for the magneto is suggested by a reader, and illustrated in the issue of the good old *Motor Cycle* for January 30th. Perhaps he would be interested to know that such a drive exists on my $4\frac{1}{2}$ h.p. twin Minerva, and also that it is quite satisfactory. Whether this was fitted by the makers or added since, I do not know, but I understand the old 'bus won the Jarrott Cup somewhere about 1913, so it may have been a special fitting.

LEONARD S. MASON.

[The Minerva drive referred to was standard, but differed considerably from that illustrated on page 107.—Ed.]

BENZOLE.

Sir,—I notice in two places in your issue of January 30th there is a complaint as to benzole being of poor quality from a motorist's point of view. I think if the producers would put benzole on the market it would simply walk away from petrol (war time), but I am sorry to learn that the toluol is not being taken out, and it will mean more sooted plugs after a few miles run.

Now as a user of benzole for a considerable time, it was my experience in early 1914 that I could run fairly well on benzole with the carburettor adjusted to suit the heavy fuel, but in October, 1914, the producers started to take the toluol for war purposes, and the result in my experience was: carburettor setting the same as for petrol, and not a sooted plug for a good 1,000 miles, more power, no knock, and comparatively easy starting. Now, sir, if we can only get the late 1914 product I for one will not bother about a smell of petrol, and it is up to the benzole producers to give us the best, and we will do the rest to "encourage home industries."

98%.

Rotherham.

Sir,—I should like to say a few words as regards the benzole question. A great many motorists before the war would not use benzole, because of the injury done to their tanks, owing to the imperfect washing which was then prevalent (washing being a necessity for the production of 90% benzole). Perhaps many readers are not aware that out of each 100 gallons of crude benzole so washed and distilled only about forty gallons become available as motor spirit. Many motor cyclists have seen the splendid working results obtained with 90% benzole, but could not be persuaded to try it themselves, but we hope such grandmotherly ideas have disappeared, and that encouragement, by buying benzole, will be given to the benzole producers. All appearances tend towards the petrol combine endeavouring to control the market. By so doing home-produced fuel will disappear, thus making motoring available only for the rich.

I hope to be able, when restrictions permit, to convince motorists that benzole is superior to the best petrol. A home-produced fuel which I hope to place upon the market has the following advantages: No knocking or konking of the engine under ordinary working conditions, the fuel does not injure the tank, but, according to my experience, preserves it, and also has lubricating properties for the engine, and will give 20% better mileage with increased power, the fuel requiring considerably more air than petrol.

If the petrol combine put petrol on the market at 1s. a gallon this fuel would always be able to compete with it, for, in my opinion, when motorists become acquainted with the fuel they will not return to petrol. This fuel is and is not a substitute, and I can assure you that it will fire more readily than war-time petrol from cold, and good working results can be obtained in company with alcohol.

Longton.

MOTORIST.

REAR LIGHTS ON CYCLES.

Sir,—Re your article "Rear Lights on Cycles," as a "pedalist" I should like to endorse the remarks contained therein. I never used but one light until regulations demanded two, but I shall continue to use two lamps whether the law be repealed or not. They have no doubt prevented many an accident, both to the user and to other *habitués* of the road. Why some people should wish to abolish the rule is beyond comprehension, and it is liable to give the push-cyclist fraternity a bad name as an unsportsmanlike crowd, but I am sure the majority of cyclists neither wish to discard nor will discard the rear light. The "Hunnish" ones who would do away with this small additional extra and save a few minutes a week cleaning the lamp at the expense of other users of the road should be planked in a field together and marked "Highly dangerous."

ONE WHO WILL STICK TO THE REAR LIGHT.

Watford.

Sir,—Cpl. Elsie raises the question of red rear lamps, and without venturing any opinion as to the rights of his controversy with your contemporary's correspondent, may I assert my conviction that he is one of a very small minority in his affection for this fitment, the need for which, on cycles and motor cycles, could only be really justified when the reduction of the power of head lights to a minimum was a necessary precaution against air raiders.

The compulsory use of a rear lamp in normal times imposes an unnecessary and unfair burden on the rider, who, owing to the position of the lamp, is generally quite ignorant of the fact when the light gets accidentally jolted or otherwise put out, and he is nevertheless held to account for the unintentional and often unavoidable infraction of the law. The rear lamp law, furthermore, is a direct encouragement to the reckless or careless driver, who trusts to the red lamp to enable him to avoid collision with overtaken vehicles, and, in case of accident, can shift all blame from his own shoulders to those of the other party, by asserting the latter had no rear red light—an assertion which cannot often be disproved, unless the light miraculously survives.

There are a few motorists (I ought to say motor carists) who claim that because they are compelled to carry a rear lamp so ought all other vehicles, but I am sure the majority recognise this to be a false claim, as the primary purpose of the rear lamp on a car was not to show a red light but to illuminate the number plate.

I would suggest that carists should agitate for the law to be amended to allow them to illuminate either back or front plates at their discretion, like motor cyclists, and to combine with motor cyclists and cyclists, and indeed all vehicle users, to advocate the abolition of red lamps for any sort of vehicle, and the definite acceptance of the principle that the onus of responsibility for avoiding collision rests with the overtaking driver, whose speed should be no greater than his head lights justify.

GEORGE E. L. SHERRATT.

WHICH TYPE?

Sir,—Your correspondent "One of the Old (Motoring) Gang" has touched on a subject which has been written about time after time, and, in spite of it all, the majority of manufacturers to-day still cling to nickel-plated handlebars, etc., in the same way that they do to the glorified push-bicycle type of front brake.

As manufacturers are now advertising the fact that they have gained a vast amount of experience during the past four years, surely they must, by this time, have come to the conclusion that there is far too much nickel on the average motor cycle. If they have not, let someone stick a pin in them, and try and turn a small part of their revs., torque, and valve-timing thoughts towards common things like mud, rain, and rust.

About eighteen months ago, I was in a Red Cross hospital, where all the table knives were of rustless steel, which never needed cleaning, never rusted or stained, and were always bright. If we must have bright parts, why not rustless steel?

I agree with "One of the Old (Motoring) Gang" that enamel is far better than nickel plate, especially if one does any amount of all-weather riding or lives in a "dreary and rain-swept part of the globe" like "One of the Old (Motoring) Gang."

DON PIP.

Colchester.

ADVANTAGES OF A TWO-STROKE.

Sir,—I belong to that class of "would-be motorists" to whom the cost of the present high power combinations is prohibitive.

I was exceedingly interested in Mr. F. W. Varney's letter of February 6th describing his experience with a 2½ h.p. Levis and sidecar. Now this is about what I want, but is it really a feasible proposition, as the opinion of my motoring friends seemed to be summed up in "Well, old man, of course, it can be done, but it simply lugs the engine to bits in a season."

That "lugging to bits" process sounds a bit expensive in repair bills.

I may say my weight is 12 st. and passenger 10 st., roads good, and hills moderate. I do not, of course, expect speed, but I do want reliable, economical running. Can some readers help me with their experiences with 2½ h.p. and light coach-built sidecar, with some idea of the running expenses?

Luton.

ENQUIRER.

Sir,—I hope your readers will forgive me for again bringing in the long-discussed topic of average speeds. But surely the average speeds which F. W. Varney claims in your issue of February 6th are, to say the least of it, a trifle tall for a 2½ h.p. two-stroke.

Surely "F.W.V." does not seriously claim to have averaged 35 m.p.h. with a coachbuilt sidecar attached. May I enquire over what distances, and under what conditions, this speed was attained?

As for his claim of an average speed of 45 m.p.h. solo, surely he is mistaken. I myself ride a certain very well-known 3½ h.p. long-stroke single, with a guaranteed speed, and have never yet managed (on any machine) to average 45 m.p.h. over any distance worth talking about, although I can claim to have put up some fairly good averages over the New Forest roads before the war, but, in my opinion, a person who claims to put up such speeds over long distances is either a very good rider riding under exceptional conditions, or a road hog of the worst type, and, what is more, I am positive that no two-stroke (unless specially tuned up, stripped, etc.) could possibly average such a speed. I will admit the Levis is an admirable little "bus," but I do not think people ought to put forward such claims about a machine which is only meant for light solo work.

H.C.T.P.

Abingdon.

Sir,—What is the object of Mr. Varney's letter *re* the Levis? Every experienced motorist can only think "it may be true, but —," while many would-be motorists can be very badly misled by it. Personally, I must say it reads like a bad bit of "leg-pulling." Any motorist knows the Levis pulls well, but the makers will not thank Mr. Varney for claiming it to have the powers of a 5-6 h.p., or even a 7-8 h.p. twin. If the gradients mentioned are "dreaded" hills, and he can take up three passengers besides himself, I suggest he send his engine back to Messrs. Butterworth at once to be carefully investigated by a committee of experts, to discover the reason of its phenomenal powers. If his statements are accurate, we now know that the highest power any motor cyclist wants can be achieved by a single-cylinder of Levis dimensions, formerly absurdly rated at a 2½ h.p. in error. May I also congratulate both rider and engine on the remarkable average speed attained. Taking present-day roads into account, the makers must have presented him with a special frame as well as a special engine, to take a sidecar with three passengers at anything approaching 35 m.p.h.

H. F. MOHUN.

THE FUTURE OF SURPLUS GOVERNMENT MACHINES

Sir,—Having read your contributor "Cantab's" article and the letter from H. Haskins on this subject, I have come to the conclusion that it is high time someone put in a word on behalf of the "riders" as distinguished from "trade" interests.

Nothing, to my mind, would be so infinitely bad in policy or so conducive to a continuation of profiteering, as for the Government to allow the trade to "scoop in" all or most of these war-worn machines at a flat rate, so that after being repaired they can be resold to the public at an immense profit. "Cantab" must have had his tongue in his cheek when he naively suggests that this proposed method of disposal is mainly to protect the trade. He anticipates then that the private buyer would be on a good thing by purchas-

ing directly from the Government. I am afraid this kind of proposal is not very convincing, and the only consolation "Cantab" can offer after the poor shorn lamb has been fleeced is the makers' guarantee.

It would be interesting to know what makes Mr. Haskins so firmly of the opinion that no one except the makers would be able ever to get the machines in satisfactory condition again. His suggestion about controlling profits is — Well, now, how could anyone control profits on the resale of machines whose condition, when purchased from the Government, ranges from "scrap iron" to, say, a punctured tyre?

No; the only right and proper way to dispose of surplus war material is to sell by public auction to the highest bidder after reasonable notice, and I think you will find that you have a tough job in trying, as you have been latterly, to convince the majority of your readers to the contrary.

I may add that I have no connection with the motor cycle industry.

SUNBEAM.

THE CONTROL OF AEROPLANE ENGINES.

Sir,—May I venture to criticise some of the remarks made by "Torque" in his article on the control of aeroplane engines in your issue of January 16th? To begin with, he is always very vague as to the type of engine upon which he is discoursing, and it is quite hopeless to attempt to make any statements applicable to all aero engines. Not only every make of engine, but also every individual engine itself, differs to some extent from every other.

With reference to his statements in regard to oil pressure, I am afraid I can hardly agree with him. Some engines have two oil-pressure gauges—high and low. It is only on the low-pressure gauges that I have ever noticed the pressure to be excessive when starting up from cold. Most engines have just the high-pressure gauge, and this, when starting up from cold, almost invariably gradually attains its correct pressure, and there it sticks, unless there is a leak or an obstruction in the oil circuit.

I have never seen or heard of anyone stopping an engine after a three or four minutes' run to allow the oil to warm up; and in my experience, even in the coldest weather, the oil is always sufficiently warm to permit of running up by the time the water is warm.

Then with regard to the rev. counter. Almost every engine has its own set of revs. It is very rarely that any two engines do the same number of revs. when going all out. Also different pilots have different opinions very often as to the normal revs. of the same when flying level. Some always rev. an engine much faster than others.

Then, again, I have never heard of an engine being run up and down on each separate ignition system. Just run the engine to its full ground revs. once and have done with it, or else it will probably be so hot that it is boiling after climbing a few hundred feet. Very often, if the pilot knows his engine, he does not run it all out on the ground at all, but only runs it up sufficiently to make sure it is firing quite evenly and is pulling steadily.

If the pilot wishes to gain height directly he takes off, he will usually open right out while actually getting off, and then throttle back a little.

May I add that with the average stationary engine a pilot is very unlikely to lose his prop. when descending, as the throttle should be set so as to tick over nicely on the ground when pulled right back? I hope "Torque" will be more explicit in future.

R. A. BUTT.

BOOKS FOR MOTOR CYCLISTS

MOTOR CYCLES AND HOW TO MANAGE THEM.

The recognised standard text book of the motor cycle: deals with all types of machines and with every part of the machine. 400 illustrations.

Price 2/6 net. By post, 2/10.

HINTS AND TIPS FOR MOTOR CYCLISTS.

A valuable collection of useful "wrinkles" and items of information concerning the running, management, and repair of motor cycles.

Price 2/- net. By post, 2/3.

TRACING TROUBLES.

Motor Cycle Faults, Their Identification, and Their Remedies Fully Explained.

Price 2/- net. By post, 2/2.

Obtainable by post (remittance with order) from

ILIFFE & SONS Ltd., 20, Tudor Street, London, E.C.4
or of leading Booksellers and Railway Bookstalls.

BRAKES

SOME CRITICISM AND SUGGESTIONS FOR SIDECARS

THE war has not done much in developing the efficiency of brakes. Much has been learned from the conditions obtaining in the war zone as regards the strength and durability of frame design, while the development of the aero engine will doubtless have a widespread effect on petrol engines of all kinds. But what about brakes? Aviators do not require them, neither do the majority of military motor cyclists. The latter figure for the most part in flat country, where the mud or the dust or the sand pulls them up whenever they close the throttle. Their trouble is not in stopping, but in keeping going. If the conditions happen to be more homelike, then the most they require of the brake is an occasional retarding effect, such as is required in traffic or in ordinary flat country touring. Any variety of brake will do this, but the brake for the heavy touring machine must do more—it must be capable of holding the heaviest load for long periods of grinding stress; of not only holding, but of bringing the machine to a standstill at any time, and of doing this day after day without rapid depreciation or loss of efficiency. The war did nothing to develop brakes, chiefly because the heavy sidecar machine was not much used in the Services, and where it was used brakes were seldom required. In a certain part of France at one time, however, motor cyclists were well qualified to discuss this subject.

A Searching Test.

The men rode heavy outfits, with three-up, and their riding mainly consisted of a mountain descent of eight kilometres and the necessary return. The descent was of an unrelenting houseside variety, with hairpins innumerable, the roads were crowded with transport, and often the journeys were made in darkness or under heavy fire. If ever men required good brakes on their machines these men did, but they lost all

One of the most difficult climbs in England—Hardnott Pass, Cumberland, and the venue of many hill-climbing parties before the war.

interest in such attachments. The machines they rode possessed what is unquestionably the best brake on the road, but so that it should retain gripping power it was necessary copiously to inject petrol every trip, and, as the friction surfaces were inaccessible, the natural result was that the existence of the brake was ignored.

On any one of the machines one could stand on the pedal with one's full weight on even a moderate portion of the gradient, but with top gear engaged it was impossible to hold the machine. Consequently the clutch with a stationary engine was forced to serve as a brake. In one of the pre-war six days trials, after four days, 90% of the brakes struck work, and the gears were forced to perform two functions.

The Clutch as a Brake.

One learns to become pretty handy with one's gear lever, but the system is not good. The dog teeth of the clutch are only deep enough to stand the torque of the engine, and the additional strain of braking soon begins to tell. There comes a day when the low-gear dog jumps, and when once it has jumped it can never again be depended upon. It will jump when most required to hold, plunging one headlong into a train of *ravitaillement* or over the edge of a precipice. Moreover, though the immediate retarding effect of slamming in a low gear is great, it is not lasting, and after the first sudden drag, the first acceleration of the engine being completed, the machine proceeds to gravitate, while, over and above all this, the efficiency of the engine as a brake is no excuse for the inferiority of the brake itself.

Now the effect of the clutch on a *stationary* engine is excellent in its strong and progressive retarding effect, taking it, of course, that the compression holds. No brake can compare with the clutch in performing that function, it wears well, and can be depended upon

Brakes.—

for long usage. This leads one to think that the best type of brake for heavy sidecar outfits would be of the metal plate variety contained in the back wheel. It would be heavy, of course, but so, for that matter, is the metal-to-metal expanding, and as regards expense—well, most sidecar riders would not object to parting with the dubs to ensure the possession of a sweet, durable, and powerful brake. Indeed, I think there is nothing more distressing for the ordinary amateur sidecarist than that feeling of insecurity which arises from lack of confidence as regards stopping the machine. With solo machines the simplest type of brake is the best. It is a visible, open air proposition, easy to rejuvenate, and practically infallible.

A hand brake one could notch would be a most valuable fitment for a sidecar machine, though, of course, useless for a solo mount. By sidecar machine I mean any type of vehicle that can be classed under the same heading as the sidecar, though really we have less to grumble at than have the light car people. I have driven light cars which one simply could not hold even on a moderately severe West Riding gradient, one or two small Americans being absolute horrors

in this respect. On drawing back the brake lever a rather harsh grinding noise issued from the vicinity of the rear wheels, but otherwise nothing happened. The car proceeded at its own sweet will towards whatsoever peril lay ahead, while one well-known make of light car, when driven solo, merely proceeded to jump about the road when the brakes were applied, and the more urgent the need for immediate deceleration the greater were its convulsions and the more unmanageable it became.

We conclude, then, that the ordinary tourist values a good brake above most things, and is quite willing to pay for one which will wear indefinitely and can always be relied upon. The expanding ring principle is doubtless the best at present employed, but it needs to be of ample dimensions and placed in such a position that it can easily be washed out, otherwise it will become inoperative owing to old oil and foreign matter fouling the friction faces. I believe that a simple design of plate clutch brake which could be more or less roughly made and readily adjustable would beat the expanding ring for durability, reliability, and sweetness of operation. Who will try it?

CHINOOK.

MOTOR CYCLING DISCOMFORT.

A Criticism and Some Suggestions for Designers.

NOW that post-war programmes are in the air and manufacturers are endeavouring to remember how a motor cycle was made, the time is opportune to call once more for special attention to a very important but much overlooked point in design. I refer to the question of fitting the machine to the rider. As things stood in 1914, a motor cycle was made in one size of frame to suit every rider whether a guardsman or a bantam. The adjustments provided, *i.e.*, saddle, bars, and, in some cases, footboards, were presumed to be sufficient to accommodate all riders. In consequence, only one rider in ten rides in comfort; the other nine put up with aching backs and wrists, cramp, saddle soreness, and all the discomforts which bad design coupled with bad roads can produce. I am a tall rider, over 6ft., and have never yet ridden in real comfort. A modern W.D. machine gave the best position I have found, and even that was tiring on long spells. The back foot-rests were almost directly below the saddle, and the boot heels hitched on, well—a T.T. position, in fact, but not to be recommended for long touring rides. Generally, my feet stick right forward on the front end of the footboards and perform a continuous step-dance.

Illustrating the extreme range of adjustment necessary to enable men of various heights to ride in comfort,

of 2in. to 3in. in the height, and the usual adjustments for position would then be sufficiently effective to satisfy most riders.

"Chinook" recently suggested several designs for adjustable footboards, and whilst they were a step in the right direction, they did not completely solve the problem. The directions of possible solution, as far as one can see at the present, are variable frame heights and adjustable footboards or rests. The tendency to larger ground clearance in many new models will facilitate the use of footboards giving a considerable difference in position. A variation of 6in. is not unreasonable, and a variable footboard angle is also necessary. Some riders consider adjustable bars an advantage, but general opinion is against them at the moment. Saddle adjustments should have a greater range of movement. I believe some firms have given much thought to this point in pre-war days, and they confess themselves so far baffled in finding a real

solution to the problem, but they must get down to it, or the motor cycle may find itself under a cloud of antipathy for one reason only—discomfort.

The firms who can devise some method whereby their product will be spoken of as "The most comfortable machine ever ridden" will capture a large market, otherwise lost.

The diagram merely indicates the extreme range of adjustments which are necessary to give comfort to riders of all sizes. It is a nice point as to how far the designers can go towards this ideal without unduly increasing the difficulties of manufacture and production.

F.A.S.

Some Suggestions.

The fault lies in endeavouring to fit the rider to the machine, when the machine should be made to fit the man. Perhaps it is too much to expect a series of frame heights as is available to purchasers of bicycles, and it may not be altogether desirable, but two sizes of frames could be marketed with a variation

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Water in the Carburettor.

? There is water in the float of my carburettor, and I should be glad if you would advise me as to the best method to remedy the trouble, as I think it is coming through from the tank. I may say I am using pure benzole.—A.B.R.

Water in the float is exceedingly rare; in fact, we should say almost an impossibility. A slight crack in the float will sometimes admit petrol or benzole; which, of course, must be got rid of by boiling out the petrol by immersing the float in hot water, and then soldering up the orifice. If you mean that water gets into the float chamber, the only way to stop it is to insert a very fine gauze between the tank and the carburettor which will pass petrol but not water. The tank should also be emptied and the water removed.

A Mysterious Trouble.

? I have a 4½ h.p. three-speed James combination, and recently took the engine down and cleaned it, decarbonised cylinders and pistons, cleaned valves, carburettor, and magneto contact breaker, etc. The machine was re-assembled correctly, the timing being unaltered, and a good spark is obtainable. The jet is a Senspray No. 38. Clearance between valves and tappets is correct. The machine runs well on the stand while cool, and on the road for about a mile, when it shows symptoms of overheating, and comes to a standstill with pronounced knocking. I had an expert to examine it, and he could find nothing wrong. Three different plugs were tried, without avail. Prices' oil is used liberally.—H.F.K.

Your proposition is rather a difficult one to solve without actually seeing the machine. The trouble seems to be due to overheating, which may be brought about by a variety of reasons: retarded ignition, i.e., timed late; too rich a mixture—see if the carburettor is not flooding owing to a bent needle, etc., and notice whether a great deal of air is taken. If there is not a fair quantity of oil in the crank case there will be great loss of compression after warming up, and the crank case will become hot. There may be some foreign substance in the cylinder becoming incandescent and causing pre-ignition. Have you replaced the washer under the cylinder? Omitting this, or using a thinner one, would increase the compression and, therefore, the ignition temperature. Are the valves

an easy fit in the guides and the stems clean? Note whether they are likely to bind on becoming hot, and finally, be sure there is no partial obstruction in the exhaust pipe or silencer to cause back pressure. If you have altered the gears or clutch they may possibly be working stiffly and have the effect of braking; or perhaps there is a tight bearing.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication.

ILIFFE & SONS LTD.

Hub v. Countershaft Gears.

? (1.) Would you kindly tell me your opinion about having the three-speed gear in the hub of the back wheel instead of having a three-speed countershaft gear? (2.) Is there very much difference between them when running? (3.) Where are the J.A.P. engines made?—J.C.

(1.) A hub gear is usually of the epicyclic type, which contains numerous gear wheels and working parts. A countershaft gear contains fewer working parts, much larger gear wheels, and is infinitely more reliable. (2.) There is not a great deal of difference so far as running is concerned, but the hub gear places all the weight in the back wheel which is not considered desirable. (3.) The J.A.P. engine is manufactured by J. A. Prestwich and Co., Ltd., Northumberland Park, Tottenham, London, N.17.

READERS' REPLIES.

Variable Ignition on F.N.

"H.H.T." in your issue of January 23rd makes an enquiry re adaptation of Bosch magneto, fixed timing, to give variable ignition. I had this done to an F.N. single-cylinder with very satisfactory results, and the job is quite an easy one. If a slot is cut on the timing case, extending ½ in. or so both ways from the small screw which holds it in position normally, the main part of the work is done. This slot should give the necessary

spark radius, and should coincide approximately with the sparking range of the magneto. A slightly larger screw will probably have to be substituted so as to tighten in position without actually gripping the timing case. It is also advisable to test the magneto for spark at all points in its new radius, as otherwise there may be starting difficulties. The controls I obtained ready to fit the F.N. from Earl and Co., Heath Street, Hampstead. I should be very grateful for any readers' experiences of a multi pulley (Grado, etc.) fitted to a single-speed two-stroke (Villiers engine), re ease of fitting, belt wear, etc.—JOSEPH BARRY.

In reply to your correspondent "H.H.T." in your issue of January 23rd, the above is really unnecessary if he has a two-speed machine, the engine having four cylinders. With an Amac carburettor I can throttle down to about 7 or 8 m.p.h. on top and climb splendidly. A pre-war friend of mine, a great F.N. expert, had variable ignition with a single speed, and I wanted it on my two-speed, but he dissuaded me, as he only used it slightly on stiff hills. I now find he was right. Fit new inlet springs after about 1,000 miles or so. As "H.H.T." may know, many cars have fixed ignition.

Dismantling a Gear Box.

In answer to enquiry by "J.W.O'N." on dismantling American Excelsior gear box, in January 30th issue, if he does as you mention, gets two wedges and drives them fairly tightly between the gear box and clutch, he will find that on giving the gearshaft a smart blow the clutch will easily come away. As to the kick-starter side, if he looks at the bottom of the gear case on the clutch side he will notice a hexagon head. By unscrewing this he will be able to draw the kick-starter completely away after disengaging the return springs. I would give a word of warning to "J.W.O'N." not to take the gear to pieces unless he has the proper tools with which to work, as the gears run on ball bearings, which are pressed on the gearshafts. There are no left-hand threads in the gear box or fitting.—J.E.M.

RECOMMENDED ROUTE.

HOYLAKES TO DISS.—W.H.R.

Hoylake, Chester, Tarvin, Over, Middlewich, Holmes Chapel, Congleton, Leek, Ashbourne, Derby, Loughborough, Melford, Mowbray, Oakham, Stamford, Peterborough, Wisbech, Downham Market, Stoke Ferry, Mundford, Thetford, East Harling, North and South Lopham, Diss. Approximately 225 miles.

SPARKLETS

M.P.G.

The makers of the Sun-Vitesse two-stroke guarantee a petrol consumption of at least 100 m.p.g. with their 1919 models.

Holdtite Patches.

We have received information that the Surridge Holdtite patch is being handled for export purposes by Morris, Russell and Co., Ltd., 75, Curtain Road, London, E.C.2.

Wooler's New Home.

We have been asked by the Wooler Engineering Co., Ltd., to state that during the completion of their new works at Alpertown they are occupying temporary offices in that town, and all communications should be addressed there in future.

Two-strokes in War.

The two-stroke engine has been used quite extensively for stationary purposes connected with the war. Upwards of a hundred 2½ h.p. Peco engines were used to drive trench pumps, and before acceptance by the authorities had to pass a six hours' running test on full load.

A Sparking Plug Box Spanner.

To avoid the spoiling of their brass plugs by the use of ill-fitting spanners, the Apollo Manufacturing Co., Ltd., Moseley Street, Birmingham, are prepared, on receipt of sixpence, to send to users a box spanner designed for their plugs. When asking for the spanner the name of the motor cycle in which the plugs are used should be mentioned.

A Doncaster Agency.

The makers of the Wilkinson carburetter have opened new premises at 19, Silver Street, Doncaster, as agents and repairers of motor cycles and accessories.

Temporary Address.

As a result of the recent fire at Birmingham, Messrs. S. Smith and Sons (Motor Accessories), Ltd., have secured temporary offices, at 2, Great Western Buildings, 6, Livery Street, Birmingham.

Robbialac Leaflet.

Motor cyclists who wish to re-enamel their sidecars and machines may find the instruction leaflet, issued by Messrs. Jensen and Nicholson, Ltd., Goswell Works, Stratford, E., of assistance.

New Manchester Agency.

A motor cycle depot is to be opened at 229, Deansgate, Manchester, chiefly as an agency for Norton and Royal Ruby machines by Mr. T. Davies, captain of the Stockport Motor Club.

An Adjustable Windscreen.

The makers of the windscreen described in *The Motor Cycle* of the 6th inst.—Messrs. Ollard, Westcombe and Co., 46, Great Charles Street, Birmingham—find that it will be three weeks before this fitting can be marketed, and they will be unable to accept orders for the time being.

A Useful Diary.

We are in receipt of an extremely well-got-up diary published by Messrs. George Spencer, Moulton, and Co., Ltd., which contains a few facts interesting to students of the Great War, such as a list of medals, ribbons, and decorations, which enable the ordinary person to distinguish these. Interesting facts of value to motorists are an English-French dictionary of motoring terms, a list of some of the important motor records, instructions how to register a car or motor cycle, a list of motor index marks, and a map of the Great War, Western Front.

Fuel Supply.

We are advised that Messrs. Crow Bros., 190, High Street, Guildford, are in a position to supply benzole in two-gallon tins.

British Magnetos.

At a dinner of the staff of the M-I Magneto Syndicate, Ltd., it was stated that from an output of about eight magnetos per week in 1914 the figure at the present time is nearly eight hundred per week.

New Showrooms.

Extensive offices and showrooms have been opened by Messrs. Burney and Blackburne, Ltd., at 166-168, Shaftesbury Avenue, London, W.C.2. All communications regarding the sale of Blackburne motor cycles and engines should be sent to this address.

The Bowden Brake Co.

We are informed by the Bowden Brake Co., Ltd., Tyseley, Birmingham, that the capital of the company has been increased to £75,000.

Mr. R. Melville Brown, 24a, Queen's Parade, Friern Barnet, London, N.11, has been appointed representative for London and the surrounding districts.

Messrs. Rudge-Whitworth's War Work.

Our readers will require no reminder of the services which have been rendered by motor cycle manufacturers to the nation in its hour of need. Practically every imaginable type of war implement has been produced in the different factories devoted in peace time to motor cycle production. To demonstrate the comprehensiveness of the range of war impedimenta produced by Messrs. Rudge-Whitworth, Coventry, a special exhibition was recently arranged at their London premises, 230, Tottenham Court Road. The following list contains a few of the items they have manufactured, and will give a fair idea of what has been done: A bullet-proof shield, part of aeroplane landing gear, lance bomb, bombs ranging from 16 to 230 lb., various shells, water pump for aeroplane, depth charges, barbed wire-cutters, tachometer drive for aeroplanes, carburetter for aeroplanes, shell fuzes, and aeroplane wheels.

AN EARLY BRISTOL MOTOR CYCLIST.

WHEN Mr. Herbert A. Camer first started riding he did not meet more than an average of two or three machines per week, and his friends thought that he would encounter a terrible fate on those "dreadful motor cycles, which ought to be put a stop to." We may mention that at this period he did a good deal of sidecar driving, the sidecar being a trailer with one wheel taken off and the arm bent round to make a connection to the motor bicycle frame. In this machine, attached to a twin Clement-Garrard built up of Chater-Lea parts, Mr. Camer did an extensive mileage, driving on the open country roads and in traffic from the sidecar—no mean feat in those days when no change speed gear or clutch was fitted.

Mr. Herbert A. Camer, of Bristol, and his 4 h.p. Triumph sidecar. (See paragraph accompanying.)

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—First 12 words or less 2/-, and 2d. for every additional word. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd., and crossed & Co.**

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge, which must include the words Box 000, c/o "The Motor Cycle." Only the number will appear in the advertisement. All replies should be addressed No. 000, c/o "The Motor Cycle," 20, Tudor Street, E.C.4.

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged, when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

"CHEMICO"

Have you a good tyre that's badly cut? If so, don't worry; it is still a good tyre. All that is wanted is

"CHEMICO" TYRE STOPPING

Your good tyre will be as good as ever in a few hours. It amalgamates with the rubber in the tyre, making a perfect union. CAN'T FALL OUT.

CAN'T EVEN BE PICKED OUT.

THE COUNTY CHEMICAL CO. LTD.,
—CHEMICO WORKS, BIRMINGHAM.—

Cultivating Overseas Trade.

WE recently had a visit from an Australian soldier who, like most natives of our Overseas Dominions, is thoroughly loyal to the old country and keen to buy articles of British manufacture in preference to those made abroad. He was most emphatic about the splendid way in which the American firms handled their business in Australia, the wonderful manner in which their agency businesses were run, the excellent service they gave to their customers, and their very efficient method of handling their spare parts business. He told us of a British-made motor bicycle of well-known make which had been for some months out of commission, while a spare part for an American motor bicycle could be purchased at the local store in practically any town of importance.

Of course, this may be an exaggeration, but it would show that the British manufacturer still does not take sufficient personal interest in Overseas conditions. Here is another instance: an agent in Japan writes to an American paper, "Before the war we had many English motor cycles in Japan, but they are not powerful enough to ride about this mountainous country. In addition to that, it is not convenient to get hold of spare parts of the machines as American makes. For my conclusion I will say American motor cycles are very suitable to use in Japan, and will increase in number after the war. Motor cars and cycle cars are no good for Japan." *Sic!*

This and similar comments should be duly noted by British manufacturers; it is quite time that they recognised the importance of Overseas trade—trade which should flourish not only in the British Dominions but also in foreign countries. If motor cars and cycle cars are "no good" in Japan, here is a glorious opening for the British motor cycle manufacturer. It is a thickly populated country, and there seems to be a large scope for pushing firms, and we sincerely hope

that a year hence we shall not be compelled to read such letters as the above in the American or any other journals.

The Petrol Control Department.

THERE is every reason to suppose that the Petrol Control Department will cease to exist in about a month's time. That much-blamed body has done its duty. It helped to conserve petrol when stocks were very low, and it is now but the means of collecting the advance tax of 6d. per gallon which was imposed by the Government, making the total tax 1s. upon petrol. This measure was put forward as a war expedient, and, now that the war is over, it is almost certain that the tax will shortly be removed, as it is clearly a severe burden upon the motor industry. There is now no shortage of petrol; benzole has been released from control; motor spirit vouchers, though originally intended for use in a certain month, may now be used for the purchase of petrol at any time, and it is, moreover, the intention of the Petrol Control Department to simplify the procedure. An applicant who intends to renew his licence need only write to the Department, state the number of his old licence, and ask for any number of gallons of petrol he may require, and send with his letter a cheque representing the 6d. for every gallon he demands. It is patent that this gradual relaxation must before long end in the total disappearance of control, but it is extremely urgent that the Petrol Control Department should disappear soon. It is costing the country an enormous sum to run; its *raison d'être* has ceased to exist. At the present time its sole function is to collect the tax, and the collection by such means is a very costly process. Moreover, motorists and motor cyclists have done an enormous amount for their country during the war, and it would be only just for the Government, as a *quid pro quo*, to eliminate the control of petrol as quickly as possible.

THE O.K. PROGRAMME.

Mass Production of One Model—a New 347 c.c Flat Twin.

The new 2 1/2 h.p. O.K. flat twin as it will appear when complete.

A NEW model flat twin intended for solo work will shortly be introduced to the motor cycling public by the makers of the O.K. lightweight. This machine has been designed and is being produced by Messrs. Humphries and Dawes in their own factory, and will mark the entry of this firm into the motor cycle manufacturing field as distinct from that of assembling.

The war has wrought many changes, and it is necessary to obtain a different perspective of the various makes and makers from that of pre-war days.

Nearly every motor cycle manufacturing firm has considerably extended its factory

met in the new O.K. by 26 x 2 1/2 in. wheels, which on a 350 c.c. lightweight may be regarded as ample.

Duplex Frame.

Straight tubes are used throughout the frame which is of the duplex type, and departs in several ways from conventional design. In the first place, the top tubes both slope to the rear, but the lower members which support the tank drop at a greater angle than the tube over them. This is the reverse of general practice. On this point it may be said that fashion has been sacrificed for a more scientific design.

The steering head is a somewhat massive casting webbed at the rear and embodying the lugs for no fewer than five tubes, of which the top tube of the frame is 1 1/2 in., the duplex longitudinal tubes 3/4 in., and the "down" tubes 1 in. The top tube terminates in a "seat" lug of the

conventional type, and both pairs of tubes, which are a little over 2 in. apart at their centres, connect with the single "seat" tube by neat U shaped lugs. The sloping front down tubes diverge towards the bottom in order to facilitate removal of the front cylinder, and are connected to the parallel horizontal tubes supporting the engine by means of double elbow lugs. The design at these points is shown in the drawing of the frame.

As before mentioned, there are no bent tubes in the construction of the frame. Where the rear stays are usually bent substantial castings are used on both lower and upper forks, two short parallel tubes being used to support the gear box, and a simple means of adjustment provided in the form of a draw bolt with locking nuts. The stays are made exceptionally wide to accommodate 6 in. domed guards which are deeply valanced.

The combined footboards and undershield.

during the last four years, while some have entirely outgrown the popular conception of their standing. It is permissible, perhaps, to class Messrs. Humphries and Dawes in this latter group, as while, before the war, their average output of motor cycles was comparatively small, their extensions during the past few years have increased their production capacity to between 200 and 250 machines per week.

The New O.K.

The new proposition is a flat twin solo machine, which has been designed with a view to meeting the requirements of a large section of the riding public at home and abroad. The first essential of the colonial machine is ample ground clearance, and on this point the new O.K. certainly scores with 7 in. clearance, while large tyres are another Overseas demand,

Every tube in the O.K. frame is straight. The vertical tubes of the carrier fit into split sockets on the stay ends.

The O.K. Programme.—

The 26 × 2½ in. wheels are fitted with disc adjusting hubs and withdrawable bolts, the combination of which is novel so far as motor cycle wheels are concerned.

Another feature of the frame part of the machine is the combined sheet metal undershield and footboards. The latter are covered with aluminium and are shaped and beaded at the edge. This unit is carried on the frame by two bolts, which pass through the sides below the footboards into lugs on each of the parallel tubes.

Flat Twin Engine.

From the size and general specification of the machine one expects an engine of greater capacity than 347 c.c. The first impression is that a lightweight engine is fitted in a "3½" frame, which is due, no doubt, to the somewhat long wheelbase and the 2½ in. tyres.

The bore and stroke of the opposed twin engine are 60.7 and 60 mm. respectively, and it has overhead induction valves with enclosed operating mechanism, which is well lubricated through the tubular case enclosing the long tappet rod. This system has been proved to be most satisfactory on one or two well-known engines.

Exhaust valves of generous dimensions are located at the side of the cylinder heads, and the shape of the combustion chambers and the size of the pockets should assist scavenging.

Timing Gear.

A distinctly novel system of valve operating mechanism is embodied. Two cams are formed on an internally cut gear wheel which meshes with the driving pinion. The sprocket for the silent chain driving the magneto is fixed to the cam wheel, and the complete member is supported in a long bushing bearing, which in turn is carried in a bracket fixed to the side of the crank case wall by four studs. By removing four nuts the cam wheel and sprocket can be withdrawn with its bearing.

The cylinders, which are staggered, have horizontal radiating fins, and are secured by means of two studs only. The connecting rods, on account of the staggering of the cylinders, are central with the pistons. Hoffmann roller bearings support the one-piece crankshaft, while split bearings, provided with bronze

The 2½ h.p. O.K. flat twin engine has overhead inlet valves.

bushes, are used on the big ends. The lubrication will be on the splash system. A silent chain, enclosed in the timing gear case, drives the centrally disposed magneto. The carburettor will be an Amac.

The drawing of the engine shows somewhat long induction pipes, but we understand this point is receiving further attention on the part of the designers, and that in all probability the lay-out of the induction pipes will differ from the present design.

Mass Production.

Details are not available of the gear box, but we understand that it will be of the two-speed constant mesh type, embodying kick-starter and clutch. The transmission will be by chain to gear box, and final drive by ½ in. belt. The tank will have a capacity of two gallons.

Up to the present it has not been possible to fix the price of the new machine, but we are told this will be in the neighbourhood of £50.

It is hoped, by the time the machine has passed through its tests, that the latest extensions to the factory will be complete. These will increase the floor space to approximately 1½ acres. The

lay-out of the factory is such that the work progresses in one direction from the time it enters the receiving store until finished machines emerge at the packing shops near the railway siding, which runs into the works.

The work of Messrs. Humphries and Daves during the war has necessitated installing an up-to-date plant in every way suitable for the mass production of motor cycles, and it is anticipated that an output of at least a hundred machines per week will be reached this year. Plans are being made, however, to increase this by over a hundred per cent.

War contracts included a great deal of tubular construction work, and the experience gained will be of inestimable value in the production of the new motor cycle, while it is the intention of the firm to maintain the rigid systems of inspection and the fine limits imposed by Government requirements to ensure accuracy and interchangeability. In short, the O.K. firm intend to restart motor cycle production in such a way that no lesson of war work, which can be applied to motor cycle construction, will be wasted, and that their progress will be commensurate with that of the engineering world in general.

The crankshaft assembly of the 2½ h.p. O.K., showing the roller bearings on the mainshaft, the half-time pinion, and the split big ends.

The novel timing gear. The cams are formed on an internally cut gear wheel, to which also the magneto chain sprocket is fixed.

A Commentary based upon Practical Experience and a Study of Overseas Opinions.

British Overseas Models. THERE appears to be no doubt that *The Motor Cycle* campaign in favour of British machines suitable for Overseas is to fructify this year. At last the makers of this country appreciate that the requirements of riders in Great Britain are practically identical with those of our Overseas Dominions, and are designing their new products accordingly. All-chain drive, larger wheels and tyres, increased ground clearance, larger tanks, stronger and wider guards are rules of the day both in new solo and sidecar machines which, with the several "Overseas" models produced for the Russian Government, place the British motor cycle industry in a position better to meet the requirements of the Overseas rider than it has ever been. There are signs, too, that the various trade organisations

are seriously considering questions to facilitate commercial arrangements which should be of ultimate benefit to the motor cyclist abroad.

□ □ □

Spare Parts. In short, Overseas trade as a means of increasing output and so reducing cost is now part and parcel of the future policies of our most progressive firms, and, as the supply of replacement parts is so necessary to obtain and maintain goodwill abroad, this question is not likely to be overlooked. During the past four years many of the motor cycle firms have come into direct contact with the Government Departments concerned with the furnishing of spare parts for the technical sections of our Army, and the lessons obtained must be of benefit to them in gauging the importance of the subject.

D.R.'s MIDST THE ITALIAN ALPS. Although despatch riding in Italy, Egypt, and the Near East was no mere joy ride, there must be some recompense to D.R.'s in having visited some of the most lovely scenery in the world, beheld the antiquities of Egypt, and the ancient cities of the Holy Land. With the majority of motor cyclists the opportunity of such sight seeing in the ordinary course of events would have been remote in the extreme, yet full appreciation may not be felt until they are back in humdrum civilian life.

Overseas Section.—

It may be said that one of the greatest problems which the R.A.F. had to face was the supply of spares for aeroplanes, lorries, cars, and motor cycles—a proposition rendered more difficult by the number of different models used by this branch of the Service. That the problem was solved is a certainty, and many of the men who brought order out of chaos were members of the motor industry. As to whether the methods employed can be successfully applied to the supply of motor cycle spares Overseas may be a moot point, but undoubtedly the experience has taught hundreds of men to appreciate the importance of this question, which, before the war, was treated with a certain amount of apathy.

A Selection of Letters from Readers scattered all over the World.

Requirements in Dutch East Indies.

MR. G. K. FERRES, writing from Soengei Brohol Estate, Post Tebing Tinggi, Deli Sumatra, Dutch East Indies, says:

"Am specially interested in your paper since you have started a separate section for 'Letters from Overseas.' I am a keen motor cyclist, and have had some years' experience with both a Douglas and a $3\frac{1}{2}$ h.p. Triumph (three-speed Sturmey-Archer) in this Equatorial climate.

"My Triumph I have used with a sidecar for nearly two years, and it has done marvellous work.

"I have (without sidecar) done some real hill-climbing. We have one health resort—Brastagi—which is situated about 3,000 feet above sea level, and one has to do the last 2,500 feet in the final twenty-six miles. The road is simply cut into the rock, and there are about 500 hairpin bends.

"There have been so few motor cycles in this district that some of the natives simply ran away thinking, I have no doubt, that one of their famous ghosts was at last on their track.

"By the way, I have only to emphasise the remarks of most of your Overseas riders—unless Old Britain bucks up with 28in. wheels, better springing, and different handle-bars, then even the Britishers Overseas are going to favour the Americans.

"What I want to see is an 8 h.p. J.A.P. engine on a frame like the Indian or the Harley-Davidson—with something sporting about it! Cannot you people in the 'Old Country' realise you are 'old-fashioned'? Now is the time to get a move on! Let us hear of some big factory in England turning out motor cycles by the thousand—motor cycles which one can compare with the Americans in price, appearance, and size."

Mr. G. K. Ferres and his $3\frac{1}{2}$ h.p. Triumph, to which is attached a sidecar made of "rattan."

Without doubt the secret of the R.A.F. success was its central organisation, which maintained supplies at its depots the world over. A similar organisation may be possible in connection with motor cycle spares; in fact, it is rather a matter for co-ordinated effort than one to be dealt with by each individual firm on its own behalf. Whether there should be different institutions composed of members of the retail trade in each country or one central manufacturers' organisation in the Home country with branches abroad is one for the retailers and makers to decide. However, something on these lines would be of great assistance to the private Overseas buyer, and unquestionably prove another attraction to the purchase of British machines besides stimulating the trade.

Appreciation.

MR. P. KYLE, writing from Mbulamuti, Uganda, Central Africa, says: "I am writing to express my gratification for the page of photographs of 'Summer Scenes in Many Counties,' in *The Motor Cycle* last summer.

"A few photographs like these are 'as cold waters to a thirsty soul' to us exiles on the outposts of Empire, and are a pleasant diversion from technical articles on valve designs and front wheel springing, although I quite appreciate the fact that you have to cater for all tastes.

"I hope we shall have more of these photograph pages in the future."

Illuminating Criticism from Ceylon.

REV. A. M. WALMSLEY writes from Ceylon on several subjects of topical interest:

"I am glad that from time to time you take up the question of sparking plug design, and trust you will continue to urge the British manufacturers to improve the quality of their productions. Doubtless the war, especially in the air, has taught them much; but, so far, I believe, none of their improved methods has borne fruit in Ceylon. My own experience may prove interesting.

"Some time ago I put into the front cylinder of my Powerplus Indian a single point English plug, made about 1914, and practically new. Soon afterwards I noticed, in climbing a tricky pass that rises about 1,000 feet in three miles, that misfiring set in after the first two minutes, and unless I changed down at once the machine conked out. Thinking the engine was foul, I decarbonised, and put thick washers under the cylinder bases. On attempting the hill a second and third time, with a clean engine and reduced compression, I found that the same thing happened again.

"On removing the plug I saw that the central electrode looked as though it had been heated to white heat in a furnace, as, indeed, it probably had! I substituted a single point Splitdorf plug that had seen good service. Four or five times since then I have had to climb the same pass. There has not been the slightest sign of distress on top gear, except on my part, when I found I was cornering too fast, and likely to break my neck! I have had to scrap the troublesome plug.

"Re twist grip controls, mentioned by Mr. Merlin in your issue of January 10th. I am with him all the way. Ceylon probably provides as tricky riding as most countries, and, to my mind, there is no comparison between the English and American methods of control. For how many years has 'Ixion' been grousing about 'tap-twiddling'? Give me a handle which I can grip with the whole of the hand whilst controlling the machine, and no danger of the wires rusting up after a monsoon downpour. The latter trouble has nearly caused an accident more than once.

"And what is the matter with the automatic carburettor? Has not 'Ixion' been shouting for this for ages? Somebody said in *The Motor Cycle* recently that the automatic carburettor and twist grip control conduced to careless driving on extravagant mixtures. I do not see it. Take the Schebler carburettor—adjustable jet; by-pass (with the effect of a pilot jet) also adjustable; hot air intake; extra air intake; high speed adjustment, etc. The adjustable

Overseas Section.—

jet, extra air intake, and high speed adjustment are easily reached from the saddle, and indeed I usually tune up my carburettor whilst driving, with a hot engine, to suit elevation above sea level, temperament, or any other 'error of the day.'

"A short time ago I drove my Powerplus seventy-five miles up a climb of 6,000 feet on just about one and a quarter gallons of war petrol. I do not want anything better than that.

"Lastly, with regard to 'Goods Made in Germany.' I hope you will stick to your resolution. Personally, I do not see how any right-minded man on the surface of the globe can have anything to do with either Germans or German goods for the rest of his life. For my children, who are mercifully too young to know what is going on, it may be possible; but, for me, with the thought of a thousand unbelievable horrors burned into my memory, never!"

Spares and Repairs in India.

MR. F. W. HENDERSON, Sind, India, writes: "I have been very interested in the remarks of correspondents regarding the requirements of Overseas riders, such as 28in. wheels, good ground clearance, strong countershaft gear, and full chain drive. (For preference, I would prefer a shaft drive.)

"Among the many suggestions made, I do not ever remember one on the difficulties of maintaining a cycle in good running order or of having repairs properly executed. (I confine my remarks exclusively to India.)

"The so-called garages out here can carry out the decarbonising jobs, painting, enamelling, or changing bearings; but when it comes to a general overhaul, one has to be very careful to whom a motor cycle is entrusted.

"I know a firm of so-called motor cycle repairers and accessory dealers who did not know how to retune a machine when the timing gear had been upset. The firm had to borrow a 'Hints and Tips,' and finally I did the job in return for a free charge of petrol.

"Now, sir, this leads me up to the object of which I am writing to you.

"Manufacturers place machines on the market in India. They are purchased. They run. They wear, and get neglected, and the end is a breakdown. They go to the garage, and, after a few months of trouble and much expense, they are sold as duds, only to be doctored up and put on the second-hand market as thorough-going reliable machines, but in reality 'fakes.'

"Now, why do not English manufacturers combine to have a reliable representative (a practical bench mechanic) at Bombay, Calcutta, and Lahore, or even Karachi, fully

equipped with spares, and fully conversant with the types of machines he represents? My contention is that riders out here could then have repairs properly done, and manufacturers' wares would be saved a bad name. The Indian untrained, self-taught mechanic, undertakes a job, and the owner of the machine condemns the job and the machine as unreliable.

"Two machines suitable for work in India are the Overseas and the L.M.C. A friend of mine rode the former and I possess the latter machine. It has done 15,000 miles in twenty-one months. It has been entirely ridden, overhauled, and decarbonised by me. I have had to change nothing beyond the automatic variable driving pulley. I do not hold a brief for the L.M.C. people, but mention this to prove the necessity of manufacturers combining to place qualified mechanical men as representatives in the chief cities of India: men who could push business and be capable of guaranteeing a repair. I am a railway man, and thirteen years in India have proved to me that, with a leader to guide the Indian mechanic in the repairs to motor cycles or car engines, it is possible to make him as qualified as he is at locomotive repairs. At the present time all motor cycles in India live on the reputation gained in England.

"Now that the war is over, we may see a great change in opinions regarding things motor cycling. Personally, I cannot understand why the L.M.C. is not more in evidence, as it is an exceptionally fine machine for overseas work."

Overseas Trade.

"KANGAROO," writing prior to the Armistice, says: "It is agreed that when the war is over our greatest national need will be the highest possible measure of production. In no other way can the vast war bill be liquidated. Without a market, however, production is not wealth; therefore, co-equal in importance with production itself is efficiency in marketing.

"Where America and Germany, in pre-war days, outdistanced the British was in the marketing, and had British goods been of better quality than that of their greatest competitors, the race for commercial supremacy would have been lost. The valuable asset of Britain's reputation for good quality is most valuable to the country, but British quality plus more up-to-date business methods would render our position more secure.

"In pre-war days the Britisher had the advantage of a preferential tariff, yet did not succeed in holding his own, but *there may not be a preferential tariff always.*

"Certain it is, the old comfortable, happy-go-lucky kind of world we knew in July, 1914, has vanished for ever. The Prime Minister once said that 'we must go on or go under.' Let every manufacturer apply those words to the wider outlook of the future."

MOTOR CYCLES IN SPAIN.

A Big Potential Market for British Machines.

IT would appear that there is a promising market for English motor cycles in Spain. The actual number of machines now in that country cannot be given accurately at the moment because the Government has only just insisted upon a complete registration, but there is no doubt that the number is increasing rapidly, though unfortunately, from the British point of view, the majority of machines reaching Spain have necessarily, during the past four years, been of American origin, chiefly Indians and Harley-Davidsons. Previous to the war, however, the better known English makes, such as the Douglas and Triumph, were greatly favoured.

Opinions of a Britisher in Barcelona.

We recently had an interesting talk with Mr. Harry Walker, of Barcelona, who represents a large number of British accessory firms in Spain, and who is very closely in touch with motoring generally in that country. Mr. Walker laid stress on the necessity of English manufacturers making every effort to get back their pre-war standing in the Spanish market.

At the same time he remarked that the present popularity of American machines is not necessarily entirely due to their own merits, but largely to the fact that their makers adopted the policy of stocking with spares and supplies, not only the

principal agent in each province, but also a certain number of carefully selected sub-agents, the result being that the Spanish buyer is usually satisfied with an American machine, instead of, as has often been the case in the past, having to wait a considerable time for a British machine, which frequently it was necessary to order.

With regard to sidecars, it would appear that these are exceptionally popular, and in fact the tendency is to buy high powered motor cycles with sidecars attached. The English-made sidecar is infinitely superior to that of any other country and this fact is well appreciated by the Spanish buyer, but, unfortunately, the duty is three pesetas per kilo., which is approximately equivalent to 4½d. per lb. This high duty renders it difficult to sell any great number of British-made sidecars, because the price of the complete outfit necessarily becomes very near that of some of the cheaper local light four-wheelers.

In these days of high prices it may perhaps seem Utopian to talk of any sort of four-wheeler to sell under £100, but Mr. Walker is emphatic that if it is possible to make a cheap form of cycle car, particularly one possessing a sporting appearance, to sell in Spain at less than £100, there will be an immense demand in that country for such a machine.

Motor Cycles in the U.S.A.

There are over 20,000 motor cycles in use in the State of Ohio alone. It is expected that this figure will be increased by 50% during 1919.

The Motor Legislation Committee.

The Chairman of the Motor Legislation Committee, which has been organised to deal with questions affecting motor users, and has arranged a conference to consider the present-day regulations, notifies the organisations concerned of the resolution that representation on the Committee shall not be conditional upon subscription to its funds, and extends the invitation to the associations to provide representation on such Committee.

Manufacturing Assistance.

The largest manufacturers of motor cycles are not all in the best position to resume production of the staple goods. A few weeks ago we referred to one large firm requiring manufacturing assistance, and we have been able to place them in touch with engineering concerns who could undertake such work. We now hear of another important motor cycle manufacturer who requires similar assistance, either in making complete engine or gear units, or the entire machine.

The Sky-pilot.

We heard recently from Mr. R. M. Bankes-Jones, who is now a pilot in the R.A.F. He was formerly curate at Sunningdale, Berks., and a frequent contributor to this journal before the war. He writes: "Congratulations on the new lease of life *The Motor Cycle* has taken on, after surviving the war period. There are sure to be big days ahead for the motor bicycle. I have been in the Egyptian Expeditionary Force since last May, and do not know when I shall return to the United Kingdom. In any case, I shall be sorry to give up flying when the time comes. So far I have flown the old Rumpety, D.H.6, D.H.9, Avro, Pup, Camel, Bristol Fighter, B.E.2C.D.E. and 12, R.E.8, 90 and 160, A.W. S.E.5, but not a Handley Page yet!

The N.M.C.F.U.

The Sheffield branch of the Union will hold a meeting on March 29th, and a lecture will be given by Mr. L. B. Henderson, A.M.I.A.E., on March 15th. The venue in both cases is the Imperial Hall, Pinstone Street, Sheffield.

The Late Mr. E. Powell.

We regret to record the death of Mr. Edward Powell, which occurred in London on February 16th. Mr. Powell was a well-known figure in the motor world. He was president of the S.M.M.T. from 1914 to 1918, and formerly associated with the Humber Co.

St. Thomas's Secretary Honoured.

We offer our hearty congratulations to Mr. G. Q. Roberts, secretary of St. Thomas's Hospital, on being awarded the C.B.E. Mr. Roberts is the head of a motor cycling family. His eldest son, C. Q. Roberts, was well-known in the motor cycling world as a skilful competitor on a Blackburne in competitions prior to and during 1914. He enlisted as corporal R.E. at the beginning of the war, and was later killed in action. His other son is also a keen motor cyclist.

Special Features.

TWO NEW FLAT TWINS.
FROM KILIMANJARO TO NYASA.
PREPARING FOR THE ROAD.

What is it?

A French sporting daily advertises in the second-hand column a "Sidecar, Triumph-Rudge, 1450 francs." It would be interesting to know what sort of machine this is; some weird transformations have occurred in connection with military machines "over there," but a Triumph-Rudge sidecar combination is somewhat mysterious.

Rover Prices.

The 1919 prices of Rover motor cycles are now announced, and range from £67 to £132 10s. The former price is for the single gear model. With hand controlled Philipson pulley the price for the 3½ h.p. is £72, and with three-speed countershaft gear £85, the 3½ h.p. sidecar outfit being £117 10s. The 5-6 h.p. twin machine is £100, and £132 10s. with sidecar. The sidecar alone is £32 10s.

How an American motor cyclist solved the garaging problem. A block and tackle was fixed to a specially constructed supporting beam and used for getting the machine in and out of the basement.

Velocette New Prices.

The revised price of the 2½ h.p. two-speed Velocette is £48 and the ladies' machine £50.

New Flat Twins.

In this issue we give particulars of the new O.K. and the Harley-Davidson flat twins, which differ considerably in one respect at least. The former has a somewhat long wheelbase, and that of the latter is exceptionally short.

Coming Events cast their Shadows before.

"These commodious premises, suitable for club, public institution, or conversion to flats, to be sold (with early possession); floor space about 20,000 feet super." This notice is shown outside the Petrol Controller's premises, Berkeley Street, and no doubt foreshadows an early demise of this Department—an event which is already overdue.

Benevolent Fund Concert.

The Birmingham Centre of the Cycle and Motor Trades Benevolent Fund had a crowded house at their tenth annual Bohemian concert at the Temperance Hall, Birmingham, on the 21st inst. The chairman (Mr. Boulton Brooks) and secretary (Mr. A. C. Huckstepp) reviewed the splendid work of the past year, 300 new members being enrolled and £550 disbursed. The fund gives substantial help to unfortunate trade members. Mr. W. A. Standing, editor of *The Motor Trader*, and Mr. J. B. Clarkson, of New Zealand, also spoke. The latter intends forming a Colonial branch of the fund on his return "down under."

A Motor Cyclist in Charge of a Siege Battery.

W. S. Fitchett, who, before the war, was manager of the repair department of the New Hudson Cycle Co., Ltd., writes to say that he will soon be back at his old job. In 1915 he was enlisted by the Editor of *The Motor Cycle* in the M.G.C. and afterwards obtained a commission as a workshop officer R.A.S.C. (M.T.), having charge of a mobile workshop in France. Later on he was promoted O.C. to a siege battery ammunition column attached to a 12in. howitzer battery using 120 h.p. caterpillars.

W. S. Fitchett, Sec.-Lt.
R.A.S.C. (M.T.)

THE paper read by Mr. D. S. Heather before the motor cycle section of the Institution of Automobile Engineers at Birmingham, which we reviewed last week, formed the subject of an interesting debate.

Referring to the admitted lack of originality in design, Mr. H. Stevens (A.J.S.) deplored the policy of secrecy which had had such a retarding effect on the trade in the past. This has admittedly been largely removed by the war conditions, but there is still an

Petrol War Tax.

The 6d. per gallon war tax may be removed shortly. The R.A.C. is moving.

Benzole.

A joint Fuels Committee of the Automobile Association, the Royal Automobile Club, and the Society of Motor Manufacturers and Traders, hope to put a proposition to benzole producers which will obviate the necessity of the latter getting rid of benzole to the petroleum companies; that necessity arising in some cases because there is insufficient storage accommodation at the benzole factories and no means to distribute the fuel.

THE DISPOSAL OF ARMY MOTOR CYCLES.

No further development regarding the disposal of Army motor cycles has taken place, and last week's information is the latest obtainable at the time of going to press.

MOTOR CYCLE DESIGN.

element left which it would be better for everyone concerned to abolish. As the chairman, Mr. Lanchester, stated, where there is no originality there can be no progress.

A number of useful proposals were put forward by various speakers, such as for pressed steel chassis, pressed handle bars by the employment of which a great deal of the clip attachment could be dispensed with.

Rustless steel came in for a good deal of comment.

Miss G. K. Carlyon, who has just returned from Roumania, where she was awarded the Order of St. Stanislaus and the St. George's Medal. Miss Carlyon, who is driving the Triumph outfit with Miss Johnson in the sidecar, uses the machine to assist in running a clock factory

Hampshire Roads.

£175,000 is to be spent on the repair of the main roads in Hants.

Exports and Imports.

January imports of motor cycles (consisting mainly of parts) are three times the value of the December, 1918, figures, despite the "prohibition" on imports. The decrease of the January figures for the past three years will be seen from the appended table. The exports for the three Januaries likewise have decreased, more so with regard to machines than in the case of parts and accessories:

IMPORTS FOR JANUARY.

	1917	1918	1919
Motor cycles	£9,192	—	£58
Parts	£7,026	£3,138	£1,325
Total	£16,218	£3,138	£1,383

EXPORTS FOR JANUARY.

	1917	1918	1919
Motor cycles	£45,454	£29,454	£13,077
Parts	£33,676	£23,544	£23,224
Total	£79,130	£52,998	£41,301

It was also suggested that the short life of power units was brought about largely by bad suspension in the frame, and through faulty lubrication. This latter could be largely eliminated by taking all oil in through the hollow crankshaft and having distributing ways. Much interest was displayed in the wooden models of frames used to illustrate the paper. These very clearly indicated the results of the various stresses set up in a machine on the road, and made clear the reason for breakages in the down and top tubes.

ANOTHER AMERICAN FLAT TWIN.

The Harley-Davidson 6 h.p.
"Sports"—a Model embody-
ing many Novel Features.

The near side of the new 6 h.p. Harley-Davidson flat twin. The engine capacity is 584 c.c.

lightness. Massive bob-weights are attached to the crank shoulders by means of tapered shanks which pass right through the webs, and are secured by castle nuts. The main bearings are also on rollers, a double set being installed in the latter instance. The outside fly-wheel is built up of pressed steel discs, and to prevent the throwing up of mud, etc., it is enclosed in a neat case.

Valves.

Side-by-side valve construction is adopted, so that they may be operated from the same shaft. One cam operates each pair of exhaust and inlet valves respectively, long pivoted rockers being interposed between the cams and the tappets. A good feature is the screwed-in valve guides, which facilitate replacement. It will be seen from the illustrations that a compact and substantial construction has been obtained by incorporating the gear box with the crank case. The clutch and conventional three-speed H.D. gear are actually above the engine alongside the magneto, the power being transmitted to it by helical gearing, which should ensure noiseless action. The gears, by the way, are somewhat low compared with British solo mounts, being 5:1, 8.3:1, and 13.7:1.

To return to the engine, however, the construction of the exhaust and induction pipes should be noted; these are formed in one casting, so that the induced charge is superheated and better efficiency is obtained with present-day fuels. Their square section also adds to the neat appearance of the unit. A Schebler carburetter is used, with a special air filtering arrangement.

Lubrication.
Engine, gears, and clutch are automatically lubricated by means of a simple adjustable plunger pump, and a hand pump is provided for emergencies. The gear compartment is open to the crank case so that constant lubrication is ensured by splash. A breather hole is drilled in the intermediate gear wheel hub which

acts as a rotary valve, and a pipe leading from the top of the helical gear case feeds oil mist to the driving chain.

Clutch.

Seven steel plates alternating with six composition insert plates forming the clutch are housed inside the main helical gear, and run in oil.

The final drive is by chain enclosed in a substantial case which has an inspection window. Only one wheel brake is fitted, at the rear, and this is of the contracting band type, 7in. in diameter.

A low centre of gravity has been attained, and yet the ground clearance is ample at 5½in.

A speed of 55 m.p.h. is obtained, and we should say the machine should prove a good all-round double purpose mount.

We vouch that the performance of this new model will be watched with interest on both sides of the Atlantic. British riders will probably have an opportunity of testing the new machine before the summer is out.

The power unit of the new H.-D. Observe the twin cast induction and exhaust manifolds.

twin-cylinder engine, having a bore and stroke of 69.8 x 76.2 mm. respectively, giving a total capacity of 584 c.c. The cylinders, which are practically in line, owing to the off-setting of the connecting rods on their gudgeon pins, are not provided with detachable heads, but it is arranged so that the valves may be ground in without removing the cylinders from the engine, and the cylinders may also be removed from the engine without taking the latter from the frame. The gudgeon pin bearing is of the usual phosphor bronze bush type, and the big ends house substantial roller bearings, retained by a special steel disc and hexagon nut on the two-throw crankshaft. The piston has three rings, and is drilled in the skirt for

The adoption of helical transmission eliminates the short chains to gearshaft and magneto respectively.

THE PEACE MODEL A.J.S.

A 5-6 h.p. Sidecar Outfit with Several New Features of Design.

The 1919 A.J.S. 5-6 h.p. outfit. Many improvements have been effected both to the bicycle and sidecar.

It was first announced that the 1919 A.J.S. would be the military model "improved in minor details"; but the sum total of these alterations makes the machine as much a new design as most show models at past Olympias.

The engine, in the main, is the same as that fitted in the military model, with the exception that Messrs. A. J. Stevens have altered the cylinder design, which now embodies detachable heads, a feature of earlier A.J.S. machines, but not of the military model.

A pair of long holding-down bolts and a bridge piece as previously are used to keep the head in position, and, as in the military model, the bore and stroke are 74 x 87 mm. respectively, the total capacity being 748 c.c.

A.J.S. lubrication system, showing drilled oilways leading to the main bearings

Several other alterations are revealed upon closer examination of the engine and its component parts. The cam wheels and their shafts are now made separately, which is the result of many experiments undertaken to produce a silent timing gear. The exhaust valve lifting mechanism has been improved, and consists of two short shafts supported in bosses on the crank case, having fingers on the inner ends in contact with the underside of special discs on the exhaust tappet rods. On the outer ends of these short shafts are long levers interconnected by a stirrup in the more or less conventional way. The Bowden wire adjustment member is carried on a boss in the centre of the crank case.

A third alteration is in the angle at which the exhaust pipes leave the valve chests. They more closely follow the angle of the cylinders, and are fixed by means of screwed unions.

Parallel valve springs are now used instead of the taper type, hitherto standard A.J.S. practice.

Two alterations in the engine equipment which are immediately apparent are the changed positions of the magneto and of the silencer. The former is now in front of the engine and inclined, being carried on a saddle platform resting on two extensions of the forward engine plates. The platform is fixed to the engine plate extensions by means of four bolts, the holes in the plates being slotted, for the purpose of magneto chain adjustment.

The silencer is a new pattern. It is exceptionally large and constructed of aluminium. It is carried beneath the magneto platform, and forms a support for a neat sheet metal magneto guard.

An Amac carburetter and Thomson-Bennett magneto are standard.

A.J.S. designers do not rely entirely upon the splash system for the lubrication of the engine. The oil is delivered to the crank case through a semi-automatic lubricator, which is located on the tank. On the plunger being depressed, a spring slowly forces the oil into the usual crank case feed pipe, but it does not pass through a sight feed. After passing the union on the crank case, the oil enters a small chamber; part of the oil leaks from this reservoir into the crank case, but the major portion passes down an oil-way to the main bearing on the driving side. The bush of the main bearing is drilled, and the hole com-

A combined luggage grid and locker of ample dimensions is fitted, and the method of holding the spare wheel has been improved

(Left) The method of carrying the spare wheel on the back of the sidecar. The rim is gripped at the sides by neat clamps. (Centre) The A.J.S. gear box, showing

the built-up layshaft and multi-plate cork insert clutch. (Right) The chain case support from the carrier.

annicates with a deep groove surrounding the journal, which is always full of oil. The hole in the journal is connected with a passage through the fly-wheel to the crank pin. On leaving the crank pin the oil descends through the fly-wheel to the main bearing on the timing side.

The Gear Box.

Most of the main features of the gear box are retained. It is of the sliding gear type and several improvements have been embodied, including a lay shaft of the built-up type. The drawings given here clearly indicate the salient parts of the unit. It will be seen that an exceedingly big leverage is obtained on the clutch operating mechanism by means of a long lever connected to the end of a shaft which works in a substantial bearing; the other end of the shaft having a short arm for depressing the plunger rod. The clutch is of the multi-plate type, with two plates having cork inserts.

Although differing from the pre-war models in general appearance, a similar design of frame with sloping top tube is used. This, however, is completely hidden by the saddle tank, which covers the tube and follows a horizontal line on the top. The tank is supported on platforms on the lower tube, and is

now enamelled black, with a broad gilt line for decoration, which lends a very handsome appearance to the machine.

Interchangeable quickly detachable wheels, of the well-known A.J.S. type, shod with 700×80 mm. tyres, are fitted, while a spare wheel is accommodated on the rear panel of the sidecar. The method of fixing this wheel is exceedingly neat. Two pairs of small clips are fixed on arms which extend from the sides of the body, and grip the rim of the wheel. By loosening two nuts the wheel is quickly removed, but when in position it is held rigidly.

The newly designed exhaust lifter.

A feature of the sidecar is the luggage carrier, which is supported on the body and therefore sprung. It is of triangulated design, and constructed of pressed steel, with a wooden platform covered in sheet rubber. Beneath the platform there is a commodious locker.

The sidecar, the panels of which are of sheet steel, is particularly handsome

and capacious. It is fitted with a hinged dash, carrying the screen, which it brings well to the rear.

Other improvements include the enamelling of the handle-bar in lieu of plating, while the control wires are taken through the bar, which removes a point of complaint frequently heard against all machines with the many Bowden wires clipped to the bar.

Probably one of the most interesting features of the new model is the rear stand, which is a successful attempt to reduce the strain upon the rider in raising the machine on to the stand.

This device is extremely simple, and consists of an oval section lever hinged to the side of the stand member near its inner end. When not in use this lever lies along the stand tube to which it is clipped. When it is desired to raise the machine on to the stand, the lever is swung round towards the engine, a stop providing the correct angle; then, with the stand on the ground, the lever is pulled upwards, and the machine raised with comparative ease. Readers will agree that Messrs. A. J. Stevens are to be commended for giving this matter, so often referred to in *The Motor Cycle*, the attention it deserves, as it was practically an impossibility for the average man to raise a big twin sidecar machine on to the stand unaided.

The clutch operating lever is exceptionally long providing ease of manipulation.

The patent stand lever by which the difficulty of raising the rear part of the machine is removed.

The new magneto platform, showing the method of adjustment.

THE 3½ h.p. BLACKBURNE.

An All-chain Driven Mount with Single-cylinder Engine of 85 mm. × 88 mm. = 499 c.c.

THE new Blackburne is a worthy successor to the previous models of this make. The improvements are by no means startling, so far as mechanical design is concerned, but they are of such a nature as to enhance the appearance of the machine.

In the Blackburne engine itself there has been little alteration. As is well-known, the 3½ h.p. has an outside fly-wheel, a solid crankshaft with separate balance weights, and a car type of split big end bearing. By means of a system of oil channels, the ordinary splash method of lubrication has been made perfectly satisfactory, and the oil level is

maintained in the crank case through a Best and Lloyd sight feed lubricator.

For 1919 a Thomson-Bennett chain-driven magneto has been fitted, which is protected by a suitable guard.

The transmission is by chains, also protected by guards, but in future models they may be entirely enclosed.

Considerable attention has been paid to the design of the gear box, which is of the sliding pinion type, and is provided with an inspection plate, which also facilitates the introduction of lubricant.

The clutch is of the three-plate variety with cork inserts, and, owing to an excellent system of leverage, handle-bar control can be easily adapted. The kick starter mechanism is entirely enclosed, one stroke of the lever giving two and a half revolutions of the crankshaft.

All the frame tubes are straight, with the exception of the heavily reinforced top tube which is curved. The tank is particularly neat, and will hold two gallons of petrol and a quart of lubricating oil. The lubricator and filler caps, which latter are of large dimensions, are carried on one side so as to simplify the removal of the tank.

The mudguards are of ample width, and a small valance is fitted at the base of the rear guard to prevent mud being thrown on to the chain. The front brake is the latest pattern Bowden rim type, while at the rear an external contracting brake, lined with Ferodo, is embodied, which is provided with a remarkably

simple and effective means of adjustment.

28in. × 3in. tyres are fitted, and the wheel spindles are withdrawable. The equipment includes Brampton forks, footboards edged with aluminium, a strong tubular luggage carrier, toolbag designed to be attached to the top tube, and rear and front stands. The latter, when not in operation, forms the mudguard stay.

The wheelbase is 4ft. 1in.; height of the saddle from the ground 2ft. 5½in.; flywheel ground clearance 5¼in. The weight is 250 lb.

From its solid construction, its excellent finish, and sound design, the 1919 Blackburne should find favour with a large coterie of solo riders at home and abroad.

Kick-starter, showing inspection cover of the gear box removed.

Rear band brake of the new Blackburne.

The latest adherents to the Motor Legislation Committee are the Auto Cycle Union and the Association of British Motor and Allied Manufacturers.

Practically the first item on the programme of the Committee is the opposi-

tion to the proposed Bill shortly to be introduced to constitute the new Ministry of Ways and Communications. The matter is an urgent one, for unless the Government's intentions are altered the roads will be placed under the control of

men who are naturally in favour of railways. That our roads should be in the hands of railway men would be contrary to the interests of all, and the Road Transport Committee must see that this is altered before the Bill is introduced.

A MILITARY MODEL SIDECAR.

A Sidecar to Government Specification for Private Owners.

THE Empire sidecar is not so well known to the riding public as it is to large producers of sidecar outfits. Before the war the bulk of the Empire output was absorbed by trade requirements, and during hostilities several thousands of them were supplied to the Government for Triumph and B.S.A. machines. From this it will be gathered that Messrs. Lowe's Empire Sidecar Co., Ltd., has a larger output than is usually realised.

At the time of our visit to the Empire Sidecar works last week we saw several hundreds of these vehicles in stock which were awaiting instructions for delivery. The Government has not entirely released the company to resume their normal business, but have sanctioned their making a certain number for the public.

The military model sidecar is built under a patented process, all panels being

The latest Empire sidecar of graceful and sturdy build.

The new chassis design of the Empire sidecar. Four-point attachment is adopted, the two front supports being connected with a supplementary arm.

of special hydraulically-pressed close annealed steel, which, incidentally, makes a totally different proposition from the usual sheet metal body. The design is most pleasing and the general finish considerably above the average. The seat and back are double sprung, while the "trimming" on the sides and tops is well carried out; in fact, throughout, the sidecar is built for hard service. There are the usual large tool-chest under the seat, and side pockets for maps, etc.

The Chassis.

Designed specially for W.D. B.S.A. and Triumph machines on active service, the chassis is particularly sturdy in construction. At every point this is in evidence,

as will be appreciated by an examination of the photograph reproduced. The wheel is extra strong, with 10 gauge spokes, built on a wide dustproof hub, which has a knurled cap. All lugs are cast with webs, and the shackles are castings with oilers and gunmetal bushes. The springs are connected by shouldered bolts, so that it is impossible to tighten the nuts up against the edges of the springs. A well-stayed 5in. guard with full valance is fitted.

In every way the military model Empire is a first-class sidecar, and one which can be quickly attached and detached.

The makers are Lowe's Empire Motor and Sidecar Co., Ltd., Empire Works, Birmingham.

THE 1919 DIAMOND-JAP.

A New Lightweight with First-class Equipment.

Near and offside views of the new J.A.P.-engined lightweight Diamond o. 2 1/4 h.p.

THE D. F. and M. Co., of Wolverhampton, are the makers of the interesting shaft and chain-driven Diamond, but for the present they cannot proceed with the manufacture of this model, and are concentrating upon two-stroke and J.A.P. engined lightweights. The latter machine is a new model, and is now illustrated.

As will be seen from the photographs the engine fitted is the small single-cylinder J.A.P. with chain-driven mag-

neto at the front of the unit. The bore and stroke are 70 x 76 mm. respectively (292 c.c.).

An Enfield two-speed gear is the standard gear on this model, which is contained in an aluminium oil bath chain case, which also encloses the operating mechanism.

In producing this model the makers make no attempt to compete in price with other assembled machines which are

similarly engined, but have endeavoured to produce a lightweight first-class at every point. 26 x 2 1/4 in. extra heavy Dunlop tyres, Brooks B150 saddle, best class Bowden fittings, British-made variable magneto, Druid D.W. forks, Dunlop belt, Senspray carburetter, high quality toolbags, and well equipped tool roll are items of the specification. The makers' address is Vane Street, Wolverhampton.

The A.C.U.

As we have already stated, a travelling representative is to make an inspection by the variously appointed and proposed hotels and repairers. A Morgan Runabout has been purchased by the A.C.U. for his use.

It is hoped to be able to establish local consuls in all the principal towns in the United Kingdom. These consuls should be motor cyclists, preferably of some engineering experience, who are not directly interested in the trade, who will give advice to beginners, act as stewards at local trials, and generally represent the interests of the A.C.U. and its members. Readers who feel qualified to act in this capacity are invited to write to the secretary, Mr. T. W. Loughborough, The Auto Cycle Union, 83, Pall Mall, London, S.W.1.

Surrey M.C.C.

It is not likely that this club will be restarted as yet, owing to most of the members being still in the Forces, and there are no signs of their being demobilised at present.

The Cyclecar Club.

The Cyclecar Club A.G.M. is fixed for March 24th, at the Royal Automobile Club, when the officers and committee will be elected. It is also proposed to alter the title to "The Junior Car Club."

Bolton and District M.C.

A successful opening meeting was held on the 13th inst., and the officials elected. The committee intend to hold a dinner at an early date at which some prominent speaker, probably an A.C.U. representative, will be present, as a recruiting measure among the local motorists. Intending members should send their names and subscriptions (5s. 6d., including affiliation fee to A.C.U.) to the hon. secretary, Mr. J. E. Whittaker, 205, St. George's Road, Bolton.

Italian Clubs.

The paper *La Gazzetta Dello Sport* has organised a long-distance trial, to be run in May, from Milan to Naples—about 530 miles.

The Moto Club Torino is holding a reliability trial over the Alpine pass Colle di Sestriere and a hill-climb. A reliability trial for Italian machines only, distance about 220 miles, has been arranged for the third year by the Sport Club Milan. Details of these events will be published later. The annual general meeting of the Italian Auto Cycle Union (Moto Club d'Italia) was held at Milan on the 23rd inst.

Matlock and District M.C.C.

As the majority of the old members of this club are serving with the Forces, it has practically become extinct. Here is a chance for some local enthusiast to organise a live sporting club.

Cumberland County M.C.C.

We hear from the treasurer, Mr. W. B. Anderson, West Walls, Carlisle, that as most of the members are still in the Army, nothing has yet been done towards re-forming the club.

Wakefield M.C.C.

It has been decided to re-open this Club, which was closed down "for the duration," and an attractive programme is being arranged. About twenty new members have been elected already. The hon. secretary, Mr. S. E. Wood, 186, Stanley Road, Wakefield, will be glad to hear from prospective members and others interested.

We shall be pleased to hear again from secretaries and others regarding existing and proposed clubs, their programmes, and any other interesting particulars. We are prepared to assist with advice and publicity those desirous of establishing clubs.

The M.C.C.

The largest and most important smoking concert ever organised by the Motor Cycling Club will be held at the large Queen's Hall (which will hold between 1,500 and 2,000 people) on March 21st. A number of first-class artistes will be engaged, and those who intend to be present may look forward to a most enjoyable evening.

Members of the M.C.C., and of other motor cycle clubs, may invite their friends and lady friends. Tickets may be had on application to the secretary, Mr. Southcomb May, 15, Endsleigh Gardens, London, N.W.1.

Those who intend to join the M.C.C. are reminded that they will be admitted on election and on payment of 5s. entrance fee, and that no subscription will be asked for until competitions begin. The subscription will in no case exceed £1 1s. Candidates for election must be proposed and seconded by two members, one of whom must be a member of the Committee, or provide two references.

A Labour Motor Cycle Club.

We hear of a new motor cycle club in formation in South London in connection with a Labour club, composed of engineering trade unionists and others.

The N.M.C.F.U.

Outings of the Sheffield branch have been arranged for March 2nd, Eyam, Grindleford; March 9th, Hathersage; and March 16th, Bawtry, Blythe.

At a meeting of the Coventry Branch, attended by about 250 of the members, Mr. Torkington, the chairman of the Union, in the unavoidable absence of the secretary of the Benzole Association, gave a report on the workings of this organisation, and also its specification of benzole which had been adopted as a standard. An appeal was made to all motorists to support this home production. He also touched on the proposed new Ministry of Ways and Communications by asking motorists to support the following resolutions: "(1) This meeting of executives and delegates of the National Motor Cyclists' Fuel Union, realising the superiority of rail-free road motors over any partial or extensive system of light railways, places on record its strong opposition to any legislation which will put railway interests in control of roads and road transport; and (2) all present pledge themselves to take the necessary action to warn their labour organisations that such railway control will be unfair, and will hinder independent national development of road traffic, preventing reductions in the cost of food."

PREPARING FOR THE ROAD.

Points to which Attention should be given on an Old Machine.

NINETY per cent. of the breakdowns and petty annoying stoppages that occur on the road are the result of neglect or ignorance on the part of the rider. One has only to purchase a second-hand machine now and then in order to realise this—to realise, further, the appalling lack of adjustment motor cycles have to put up with in the hands of the average amateur. How it is that breakdowns are so infrequent as they are is somewhat of a mystery, for there are thousands of men on the road who seem incapable of realising that they have a cycle to look after in addition to a motor. The modern engine is more or less infallible, requiring little attention, except for the controls, and thus, having purchased a second-hand machine, the power unit is probably as well left alone, but the cycle parts should be subjected to a most searching examination before any long distance runs are tackled.

In the first place, the wheel bearings are never in order, and on being taken adrift, as they should be straightaway, it is more or less probable that one or two broken balls will be found. After the cones have been cleaned and the bearing put together with its full complement, the hub should be packed with vaseline, and it will then require no further attention for the remainder of the season. Do not use stiff grease, for this is apt to stand aloof from the bearing, which ultimately dries and becomes foul with grit; consequently another breakage will soon occur.

Watch the Steering Head.

Few riders realise how great are the strains thrown upon the steering head when a sidecar is attached, or

Section of a steering head ball race, showing the position it assumes when the races are out of adjustment.

to what extent the comfort and safety of the solo rider is involved in its proper adjustment. Steering heads are things people frequently forget, and riding with a

loose adjustment they very soon ruin the bearings, in which case it is impossible to obtain proper steering till they have been renewed. It is, moreover, dangerous to ride with the steering head bearings out of adjustment, and, having taken the bearings to bits—by no means a difficult business—it is thoroughly worth while to renew the cones if they are at all rough or unevenly worn. At all events, the balls should be

renewed if there is any sign whatever of wear, though if the cones appear to be very little worn they can be turned round so that the maximum pressures fall on the least worn parts. A glance at the accompanying sketch shows what position the steering head bearings assume when the races are out of adjustment. If the front brake is applied the bearing is thrown violently into this position, which completely upsets the rider's control, and sooner or later either balls or races or both will be sure to break.

Attention to Controls.

Old Bowden wires are not worth troubling about, as they are a cause of endless annoyance and loss of time, though if the outer cases are good it is necessary only to purchase new inner cables, which are cheap. If the cables look worn and the strands have separated, renew them by all means, as it is only a simple soldering job, costing a shilling or two, and you are then sure of a year's riding free from control troubles, which are among the most irritating. Be sure to grease the inner cable very thoroughly before soldering on the new nipples, using some stiff grease which will be more or less permanent.

If the wires are sound, but rusted by lack of usage, the strands will break almost at once unless given attention. Take the cables off the machine, remove the wires and soak them in paraffin until quite clean and replace them, then run engine oil into the casing by making a tiny cup of insulation tape at the end of the casing, as shown in sketch. The oil can be dropped slowly into this cup, and it will then drain along the cable, the wire being pulled backwards and forwards now and then to work it through.

The tractability, fuel consumption, and general good behaviour of a machine are largely dependent on the proper working of the controls. Not only should the wires be free and well lubricated, but the return springs inside the carburettor should not be so strong that it is necessary to have the handle-bar lever adjustment screwed up tightly. The levers should move either way to the slightest pressure of the forefinger, and, provided the wires are perfectly free, very light return springs can be used. It is surprising how heavily these small points weigh in the handling of a machine, and I remember a friend of mine asking me

Preparing for the Road.—

to tune up his P. and M., which was "not going well." All I did was to free the carburetter controls, leaving them working as they should, and his later remark was to the effect: "Whatever you did, it has made a marvellous difference."

Tyre Precautions.

Do not forget the tyres. Probably you will find that water is getting into them, with the result that the rims are rusted inside. You will soon be troubled by old patches coming off or something of the kind if you use them in this condition, and the best plan is thoroughly to sandpaper the rims, then paint them. If this suggests too much trouble, renew the leather washers at the valves and security bolts (if any), and see that the lock-nuts are screwed thoroughly home on

to the washers. The slackening off of these nuts and the resultant entrance of water is a common cause of tyre breakdown.

There must be scores of riders who are now, or will very shortly be, taking out old machines, and it is thoroughly worth while to decide to spend a day or two tinkering before sallying forth. If a machine is ridden out of adjustment the trouble is rapidly aggravated, and many a good mount is reduced to a state of unreliability in the course of two or three years of neglect, when, with discriminate use, its life might easily have been trebled. I have in my possession now a six-year-old machine which has 56,000 miles to its credit, including two years of the most strenuous competitions, but which is as perfect in control and every bit as reliable—and almost as fast—as new machines from the same factory. CHINOOK.

A motor cycle ambulance used by the city of Melbourne. It is the first outfit of the kind used in Victoria.

Refinements or Small Cost?

A Plea for a Low-priced Mount shorn of Refinements.

WHICH are we to be given—refined motor cycles or cheap motor cycles? At present, production in the motor cycle industry seems to be solely devoted to models of novelty and refinement. Refinements increase while initial cost is neglected. Do manufacturers appreciate that there are two markets, of which the buyers of a cheap machine, if produced, are by far the greater in number, and yet at present they cater almost solely for the buyer of the refined motor cycle?

Reliability has come and come to stay. Now let us have cheapness. We hope and trust that manufacturers will not neglect this vast, untapped market. Let them add to the present reliability the vital necessity of cheapness, and they will find that the market is both lively and large. Surely they can see what success the Ford car has obtained from cheapness and reliability.

With labour and materials at high prices, manufacturers cannot give reliability, cheapness, and refinements in one machine. They can give us the first two in one machine, for the war has taught them the price lowering effect of quantity production. There are thousands of men and women having aspirations to a power-mount, but without the means to meet the present cost. On the other hand, the

minority who have the means and value refinements above initial cost are always in a position to gratify their desire. "Money talks," especially when laid out in a series of "gadgets." But the bulk of potential motor cyclists do not desire gadgets and novelties. They want a cheap machine of reliable quality in order that they may *ride*.

What of the Future?

Reconstruction must not return manufacturers to the "rut" of pre-war days, the "rut" in which they yearly added to the number of novelties. Let us hope that they reconstruct their works so as to cater for the two markets.

Of the two uncertainties, the future cost of fuel and the future cost of motor cycles, the former is far more likely to be lowered. The motoring classes are clamouring for this, but the potential buyers of cheap machines, although larger in number than existing motor cyclists, have no voice. They are waiting.

Will their waiting be suddenly ended by British manufacturers, or will British manufacturers let the American makers come to this country with a cheap motor cycle as they came with a cheap but very efficient car? RACH.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hartford Street, Coventry, and must be accompanied by the writer's name and address.

A SUGGESTED UNION.

Sir,—Might I suggest to M. Hitchcock that he communicate with Mr. W. Ellis, 70, Abingdon Street, Derby, the general secretary of the National Motor Cyclists' Fuel Union—a union formed for the purpose of doing exactly as he suggests, and which has already a large number of members which is increasing very rapidly. The subscription is a nominal one of 2/6 per annum with 1/- entrance fee, and four meetings are held in large industrial centres each year. We have successfully fought the cause of motor cyclists in the past, and can assure Mr. Hitchcock he can save his subscription on the first few gallons of fuel purchased through the N.M.C.F.U. W. WRIGHT.

Sir,—Will you please allow me, through your paper, to reply to M. Hitchcock re "A Suggested Union." In the first place there is a union in existence—a real fighting organisation (as will be proved in the near future), known as the National Motor Cyclists' Fuel Union, with branches in every town. It is composed of working men, and intended to look after their interests. The union is there; what is wanted is for motor cyclists to join, and so provide the force to fight. The more we have, the more ideas we have to work on, and, speaking for the Executive, the more work we have the better we like it. The N.M.C.F.U. is affiliated to the A.C.U., and these two unions are prepared to go the whole way.

T. MALLALIEU,

Honorary Secretary, Coventry Branch.

CYCLE CARS.

Sir,—The chassis lay-out of the new G.N. cycle car in your issue of the 13th is interesting, and appears to be a step in the direction of simplified construction on purely car lines. I am wondering, however, how the true alignment of the chains will be affected, (a) when one rear wheel passes over a large obstruction, e.g., a brick, and (b) when the car is occupied by the driver only, and he a man of at least moderate weight. In either case it appears from the drawing that the rear axle will be deflected out of vertical

alignment with the countershaft, or *vice versa*, and would undoubtedly result in undue strain on the chains and wear of the teeth of the sprockets.

Also a rigid drive in conjunction with a solid back axle involves the slipping of at least one of the rear wheels on corners. Will not this tend to excessive tyre wear?

Perhaps the makers will shed a little light gained from their practical road tests of the vehicle on these points which appear to be the only blots on an otherwise highly creditable design.

F. E. SCHOFIELD.

HIGH GEAR RATIOS.

Sir,—I notice that in *The Motor Cycle* of Feb. 13th, "Ixon" refers to the gear ratios on Zenith machines.

I do not, however, quite understand what is meant by the opening phrase of the paragraph, as there is apparently no challenge as far as our machines are concerned. We recognised that a 7 to 1 bottom gear was not sufficient for sidecar work or for the type of rider mentioned, and therefore the countershaft model was designed to meet this difficulty, as is stated in the paragraph referred to.

Consequently, we make two types of machines, one of which we call the standard type (on account of its being the original pattern as regards gearing), which is for the sporting fraternity for whom a 7 to 1 gear is amply low enough, and another type with the lower gear ratio called the countershaft clutch models.

The standard models have a direct drive from the engine pulley to the back wheel so that there is no loss of power owing to transmission through a gear box, and also we submit that, owing to the fact that with the Gradua gear the rider does not have to drop suddenly from one gear to the next, but can, by reducing his gear slowly, keep up the efficiency of his engine during the whole time that he is climbing a hill, there is not the same necessity for a very low bottom gear as there is on a machine of the three or four speed type, where you not only have to reduce the gear by definite steps, but also lose a certain amount of momentum of the machine during the actual period of changing gear.

F. W. BARNES, N.I.A.E.

The meeting of the Birmingham and Coventry branches of the National Motor Cyclists' Fuel Union at Stonebridge last week-end. Many new machines were in evidence and freely criticised.

LOSING ONE'S PROP.

Sir,—My attention has just been drawn to the letter from "Revs." in your issue of Feb. 13th. He asks me to name any stationary engine which a pilot can restart by diving after losing his prop. In reply, I should be much interested if "Revs." can name any engine of any service type with which this is *not* possible, assuming, of course, that the engine is in a condition to be started. **TORQUE.**

BENZOLE.

Sir,—It seems obvious that with the cessation of hostilities various attempts are being made to induce gas companies to stop scrubbing their gases for benzole.

It cannot be too widely known that this, to us, vitally necessary process involves so slight an alteration in the calorific value of the gas as to be almost negligible.

Over six million gallons of rectified benzole were produced in gas works throughout the country last year. You will agree that this is far too important a contribution of motor fuel for the national needs to be allowed to disappear. I venture, through your columns, to appeal to every motorist who may be in a position to help us in any way in this matter to communicate with me.

It is strongly felt that not only should the existing companies receive every encouragement to continue their efforts in this direction, but also that the thousands of tons of coal at present being carbonised and the gases left unwashed should also be treated for the national advantage.

STENSON COOKE,

Secretary, The Automobile Association and Motor Union.

PRICES—STATEMENT BY THE MANUFACTURERS' UNION.

Sir,—At a representative meeting of members of the Motor Cycle Section of this union, articles and letters recently appearing in the press, relative to the present and future prices of motor cycles, were fully discussed.

The opinion was quite unanimous that motor cycle prices, in the immediate future at all events, are much more likely to increase than to decrease.

The opening of the season compels manufacturers to fix list prices, in spite of the uncertainty of costs. The unstable material and labour costs render the fixing of definite prices a matter of great anxiety, and manufacturers, in their desire to keep those prices within reasonable limits, are running quite considerable risks.

It would be quite safe to say that present catalogue prices, relative to present factory costs, are much more favourable

to the purchaser than was the case in pre-war days, and yet manufacturers have to face the possibility, amounting almost to a certainty, that costs will be yet higher.

ALF. BEDNELL, General Manager,
The Cycle and Motor Cycle Manufacturers and Traders
Union, Ltd.

IS A CONTRACT BINDING?

Sir,—On page 168 of Feb. 13th, you reply to an enquirer who has paid £5 and wishes to be released from his contract to purchase. What about the other side? Surely it is equally binding on the seller.

On Jan. 1st I ordered a well-known sidecar combination at £115 from a local dealer, taking a receipt for £5 deposit, the outfit to be ready on Feb. 15th, but on calling for it delivery was refused unless an additional £10 was paid, a letter received from the makers on the previous day being shown as the cause of the increase. Protests were bluffed, I could do as I liked, but I should not get it unless the higher amount was paid, and rather than have any further bother I accepted the return of £5. What should be done if I meet with no better treatment elsewhere?

Is it a "custom of the trade" to quote one price and sell at a higher? If so let us beware "Waiting Lists."

A SCRAP OF PAPER.

FOUR-CYLINDER MOTOR CYCLES.

Sir,—When, I wonder, will a British manufacturer market a four-cylinder, shaft-driven, motor cycle as good as the F.N.? I say "as good" advisedly, because if he will make one that is truly "as good," it will be an excellent machine. Without stopping to discuss the points of F.N. design, which were capable of obvious improvement, as an F.N. rider I note with regret your pessimistic reports concerning the factory at Liège. But I hope yet that we shall see the F.N. concern revived. Many thousands of miles on a 5 h.p. F.N., with its tiny engine and despised automatic inlet (which, by the way, never gave the slightest trouble), leave me hankering only for the more powerful 7 h.p. type, which had hardly got upon the market before the crash came. That the F.N. has its own "little ways" I am well aware, but it was a worthy representative of a type which is years ahead of anything else on the market. I cannot imagine any rider who has experienced the merits of the four-cylinder engine and shaft transmission taking kindly to any other type yet in sight. Oh! for a good British four-cylinder, shaft-driven machine.

FOUR-CYLINDER ENTHUSIAST.

Indian sidecar outfits out on test. This gradient, on which many Indians are tested, is on the way to Wilbraham Mountains, and rises about 1 in 6.

MAGNETO POSITION.

Sir,—Regarding M. Hitchcock's remarks on an ideal side-car machine, and the position of the magneto behind the engine, with the contact breaker on the right-hand side of the machine, which is to his mind the correct place and way. I should like to say that this is standard practice on Dene chain-driven machines, and has been so since 1914.

JAMES R. MOORE.

Dene Motor Cycle Co.

A TABLOID HISTORY OF AIR-COOLING.

Sir,—I have followed with interest the article by "Road Rider" on the application of aero engine design to motor cycle engines, which was published in your issue of February 13th. I cannot agree, however, with his statement that "the rotary engine's inlet valve must feel like a fat pug chasing the ghost of a rat round Trafalgar Square." Now, sir, I have handled some hundreds of rotary engines of all classes in the past four years, both on brake test and under ordinary flying conditions, and have never found that one of their faults, which I allow are legion. The mixture is flung up the inlet pockets by centrifugal force, and the supply is always ample if the engine is properly looked after. One other point which does not quite tally with my experience is the statement that a rotary (and the engine in question was either a 50 h.p. or 80 h.p. Gnomé) throws out two gallons of very good and expensive oil every hour. Assuming that two-thirds of the oil used is thrown out through the exhaust valve, the total consumption is three gallons an hour. I can name a 120 h.p. rotary that uses one and a half gallons an hour, of which about a gallon would be thrown out and wasted. To conclude, I venture to say that until an efficient engine is designed to outdo the rotary for lightness and overall dimensions, the day of the rotary is not "gone for ever."

G.C., Flight-Sergeant, R.F.C.

WANTED, WEATHER PROTECTION.

Sir,—Having had six to seven years' experience of motor cycles, I am now thinking of purchasing a car.

I am, like many others, often set car-longing by the liberal mud bath one receives whilst using a motor cycle in bad weather. One of my present machines is fitted with winter mudshields, in spite of which, using the machine daily, most days this winter I return home with a most liberal coating of mud and water, from the knees downwards. All machines I have used seem the same. Cannot makers do something for us riders *re* weatherproof machines?

To return to the subject, I hesitate to change to a car, as I am doubtful of finding anything, short of the Rolls-Royce type, that will cover the ground like a powerful motor cycle, or which will climb hills without a lot of second or low gear work. I should think it a great change for the worse, if unable to take a moderate hill on top. Also, I am doubtful whether a car would stand the all-weather work, and be capable, with minimum attention, of covering even horrible roads at 30 m.p.h. All this I have found motor cycles stand, and I feel like a man changing a good servant. I should be glad of the advice of your readers.

A. W. MANSFIELD.

THE THREE-JET BINKS CARBURETTER.

Sir,—I have been most interested in the discussion which has been going on for the past few weeks *re* the "dead spot" in Binks carburetters, for curiously enough I have found this "dead spot" to exist between the pilot and second jets, and have had no trouble in getting on to the main jet. To be a little more precise, I find there is a distinct "dead spot" when the pilot is fully open, but so soon as I get a whiff of petrol from the second jet the engine accelerates in a remarkable manner. On gradually opening on to the main jet the machine literally leaps forward, and I must confess I can usually get all the power I require from the first and second, and seldom open the main at all.

I have never been able to get the ideal pilot jet, *i.e.*, one which will start the engine easily, and yet will not require extra air.

I find that if I use the next size smaller to the one I have in at present I cannot start the engine at all, or only after prolonged effort, but on the present jet I can always start easily and take a little of the extra air when warmed up.

Now closing this air or opening further makes not the slightest difference to this "dead spot," and as this "dead

spot" occurs only when the pilot is open fully I cannot see that the second jet can have anything to do with the trouble, for at this point the second jet has not come into play.

Now I do not object to using the air lever; on the contrary, I would not be without it, but if this "dead spot" could be removed I should have nothing whatever to complain of in this most excellent instrument. My machine is a 1915 $3\frac{1}{2}$ h.p. twin Zenith (countershaft), and it is still in a new condition, but I cannot give the sizes of the jets, as I am, alas, far away from my beloved machine, and my memory does not serve me. Also, I have not had an opportunity of riding it for over twelve months.

Just one word in praise of the Zenith. I have ridden it 3,500 miles without the slightest trouble, have shortened the belt twice (Who says Zeniths eat up belts?), and have always found it a most delightful machine to ride. It holds the road well, and has a good turn of speed, and will climb practically any hill. Will Messrs. Zenith Motors give us solo riders a lighter machine with a $3\frac{1}{2}$ h.p. flat twin engine and a decent spring frame? I think the gear is all that could be desired. Usual disclaimer.

F. W. MARSHALL (Lt.).

Sir,—After seeing in *The Motor Cycle* for February 6th a further letter on the Binks carburetter, I give you the following experience. During a recent Friday, Saturday, and Sunday I went 502 miles on a $3\frac{1}{2}$ h.p. three-speed Sunbeam, and used exactly five gallons of No. 3 and Scotch naphtha mixed in equal parts.

My journey was *via* Glasgow, Carlisle, Kirkby Lonsdale, Ingelton, Skipton, Bradford, Rochdale, Bolton, Preston, Kendal, Carlisle, and home again.

The "dead spot" will certainly occur with wrong jets, but with a little patience in adjusting the jets and the air slide to suit the fuel it is entirely avoided. Considering that I have mud-shields, and carried 30 lb. of luggage, in addition to riding $11\frac{1}{2}$ st., I think the economy is noteworthy, with double journey over Shap. I may also say that in 7,500 miles I have never had a choked jet or other carburetter failure, and after fourteen years motor cycling prefer this to any make I have tried. Usual disclaimer.

The roads over Shap Fell and from Kirkby Lonsdale to Settle were dangerous through ice and frozen snow. There was also a considerable amount of ice and frozen snow on the Lanarkshire roads.

With the exception of a few miles round Carlisle and a portion of Shap, the surface is quite good and a "steady" pace can be maintained.

I refrain from stating my average speed! —

Next to a reliable machine for these winter journeys, I find the chief necessities are a Thermos of Bovril, and several layers of light warm clothing.

SUNBINKS.

Balloch, N.B.

Sir,—With reference to the controversy regarding the "dead spot" in the Binks carburetter, I may say that I have used this instrument on a two-stroke, four-stroke single, twins, and four-cylinder engines, and as yet have been unable to detect a dead spot. I have lately subjected this carburetter to a laboratory test, and can still find no trace of this spot. I would suggest that if users fit the correct jets, following the simple instructions given by the makers, they will find no dead spots and will come to the same conclusion that I have—that the Binks is the only carburetter worth having.

I have no interest whatever in Messrs. Binks and Co.

London.

Reminiscences by (Rev.) F. J. Ashley, formerly Chaplain and Capt. S.A.M.C.C.

LATE in April, 1916, two hundred and fifty of us, officers and men, clambered down from the carriages of the Uganda Railway Co. at Voi, which is situated about one hundred miles inland from Mombasa.

We were immediately placed in quarantine, and camp was struck, not to journey to the front, but to depart three miles up-railway to a solitary camp in the bush. We had arrived in the country at the tail end of the rainy season, and the afternoon on which camp was struck, down came the heaviest storm local planters said they could remember for twenty years. Kits were soaked, and many mags. had no spark of life left in them. Machines were dotted all along the three-mile path to the new camp, but the mags. were speedily revived over fires the next day, and when the timing was successfully accomplished by men who had never taken a magneto down before, it was felt that the morning lectures of the two previous months had not been wasted.

A Seven-mile Column.

The fortnight spent at the new camp was passed chiefly in hunting and practising riding in column. The only road available for the latter was a narrow footpath alongside the railway, and platoon commanders had many threatened attacks of apoplexy on the approach of trains and the subsequent anxiety to see that all were clear.

To train over two hundred men to ride in single file requires patience for officers and men. Our corps stretched over seven miles in length when in line, and the difficulty was to set a pace that would allow the whole line to be moving uniformly. The leading men had to begin with a low or middle gear pace till all were moving, for experience had proved that, if the advance guard moved off in top gear, the last man to get away would have to do fifty or sixty (if he could) to catch up. With all our practice, what generally

happened was that the advance guard enjoyed itself for two hours or so and then halted to allow the others to get up.

The rearguard and mechanics had the worst end of the stick, for it was their job to attend to any rider who fell out through a "fault" he could not right himself. The rule was that men rode in pairs or sections, and on one stopping, his half-section fell out to assist, and gradually—particularly later on—the work of the rearguard degenerated into pushing on a few incompetent riders. Sarcasm and strong language were its chief assets. I offered more than once to ride behind the column and help the stragglers, but was told that my presence was a bar to the use of efficient profanity as a spur.

Through the Sand Patch.

At last, on a sunny morning, we rode down the railway and turned out on the old caravan road that led to Kilimanjaro. Every machine was loaded with kit, rations, and equipment, totalling almost the weight of a light pillion rider.

For a time we rode over a good hard road through the Bura Mountains, but when we came out on the Serengeti plains we struck plentiful patches of sand. We were to learn in time to treat it with indifference born of patience and frequent practice in riding through it, but at first it caused exasperation. I well remember the first patch; it was not fifty yards long, but soft and deep; at the time I was riding dreamily along and enjoying the breeze. It is fascinating to ride in column when all goes well. The many engines made a pleasing roar, suggestive of efficiency and vigour, my own purring and "tat-tatting" away beneath me, and the heavy pack behind absorbing the shocks of the uneven surface. The line in front of one sways to and fro in the bush until one keeps one's position without being conscious of moving controls, and all was peace. Then the road ahead dipped suddenly, and the riders one after

From Kilimanjaro to Nyasa.—

another sank out of view, and over all hung a yellow cloud of dust. When I reached the edge of the descent I saw the cause was a stretch of sand. I stopped, drew out of the line (being a privileged person), and watched proceedings. There was no hard and fast

At Kilossa (white man's grave). The hut was erected for a stay of a few days in the district.

law about sand, since it had not been met before. Some charged down into it as hard as they could go, trusting to speed to carry them through, while the more timorous or sensible dropped into low and paddled. It was comical to watch. A man would set his teeth and blind down into it, swerve violently to avoid one overturned machine, and find himself climbing the bank on the side of the road, swerve back, thrust the lever into low, and charge down into the fray, dodge again and climb the other bank, swerve back once more, feet all a-splay, dodge yet again, and then crash into another perspiring rider.

A Nightmare Ride.

"Where the —" each would vociferate, and then go down before the onrush of a third. Months later, many of us could get through long stretches of sand or in top gear without taking our feet off the boards, and leaving a furrow a ploughman might envy.

We did not travel far that day, but on the next had to reach Moschi, about one hundred miles from Voi. The road was terribly bumpy in the morning ride, and insecurely packed kits suffered. Tins of bully, knives, forks, boots, socks, all sorts of things, strewed the roads to form wealth for the local natives, since few men cared to drop out of the line and lose their position.

Darkness fell with ten miles to go, but orders were strict. Only the rearguard was allowed to stay out. It was impossible to see a dozen feet ahead. The roads were muddy and ploughed into lorry ruts a foot deep, and often these intersected. We fell repeatedly, not to mention getting into the "sluit" or ditch at the roadside.

Those ten miles were a nightmare. Once we were cheered to see a fire in the distance, but it was only placed there to divert us into another track to avoid a broken bridge over a swift-running river. Many a man wished the fire had not been there—or said he did. Men struggled into Moschi up till midnight, and after getting a man or two to help the machine on to its stand (it was beyond one man), just dropped

down into a sleep which a dozen bugles would not have disturbed the next morning. In spite of their repeated falls, the machines suffered trifling damage (chiefly twisted handle-bars and bent footboards), and the morning was given to lounging and overhauling.

We spent three days at Moschi, due to the fact that Gen. Smuts had grave doubts as to the possibility of cycles getting through to the front at Kondoa Irangi, some two hundred miles away. Ninety miles away was a place called Lol Kisale, and the Colonel was told to take twelve men and get there and back in three days as a test. The twelve best riders were chosen and accomplished the feat, though it fairly exhausted them. They reported that the roads were as bad as the one we had just traversed.

Rescuing an Armoured Car.

On the fourth day we bade farewell to the glories of Kilimanjaro and set off in high spirits for the Front. Four lorries went with us to carry petrol, spares, and supplies.

We slept from now onwards in the open, and each morning found the machines wet with dew and the pistons stuck with congealed "B" Mobiloil. Just to stand on the kick-start crank was to prove the poorest machine had an excellent compression, even on the exhaust stroke.

At mid-day we came across an armoured car stuck in a drift up to its hubs. Some fifty natives were making a feeble effort to pull it out. Fifty cyclists at once trebled the pulling power, and at the first "Heave!" the rope parted. Each cyclist lay flat on the earth, but not a native so much as staggered. The men arose in wrath and chased the natives as far as they could see them. Then more ropes were produced and some two hundred men took hold and pulled and heaved till the four and a half ton car sulkily climbed the bank.

The delay caused by the car and getting the bicycles and our lorries over the river resulted in darkness falling with still ten miles to go. There were many groans at the prospect of further night riding, though the road was not so bad now. With half the distance accomplished the Colonel decided to camp in an open space in the bush.

(To be continued.)

A native hut used as sleeping quarters.

QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Mixed Fuels.

? (1.) What is the difference between benzole, benzine, and benzoline? (2.) Will the last two run a Scott engine? (3.) If so, will they also mix with paraffin, and to what proportions?—J.R.M.

(1.) Benzole (C_6H_6) is a by-product in the manufacture of gas, being a distillate of coal; specific gravity .885 at $60^\circ F.$, boiling point $176^\circ F.$ Benzine is that fraction which comes over during the distillation of petroleum between 70° - 120° . Heptane (C_7H_{16}) is the principal constituent. This must not be confused with the aromatic hydrocarbon benzene (C_6H_6) or benzole. Benzoline is the more volatile portion obtained on redistilling benzine; boiling point about 70° to 95° ; often used as synonymous with benzine. (2.) Yes, but with the former some heating device should be installed. (3.) Benzoline only may be advantageously mixed with paraffin—about equal quantities.

Electrical.

? I am considering the question of converting a disused magneto, standard motor cycle pattern, into a lighting generator, by rewinding the armature and fitting a two-section commutator, and I would be glad to know if it is possible to obtain 2.5 to 3 amps., at six volts by suitable winding; also the correct gauge of wire for armature. Speed would probably be from 1,000 to 2,500 r.p.m. No doubt a higher speed would be necessary.—T.F.C.

Although it is not possible to say definitely whether you will obtain the output mentioned, it is quite reasonable to suppose that you may do so. The output of small dynamos is always a matter of some uncertainty, and depends greatly on the materials used and the workmanship. In a magneto machine also, the strength of the magnets is naturally a most important factor. We should recommend you to try the winding armature with No. 24 S.W.G., and see what results you get from that. Enamel-covered wire is the best, as the covering takes up less room, and so more wire can be wound on. When you remove the armature for winding, be sure to place an iron keeper across the poles of the magnet, and let this remain there until after the armature has been reinserted in the tunnel, otherwise the magnet will deteriorate in strength. You will probably find that the speed necessary will be at least 2,500 r.p.m.

Valve Timing, etc.

? (1.) What is the valve timing of a 1913 $3\frac{1}{2}$ h.p. Triumph? (2.) What position should the piston be in for giving best all-round results in timing with the magneto? (3.) What size jet gives best results for starting, speed, and economy of petrol combined? (4.) How much oil is required in the crank case when assembling the engine?—C.S.

(1.) Exhaust valve opens $\frac{3}{8}$ in. from bottom of firing stroke, and closes on top d.c. Inlet valve opens on top d.c., and closes $\frac{1}{8}$ in. up compression stroke. (2.) About $\frac{1}{4}$ in. down firing stroke on full retard. (3.) 28 or 30. (4.) A little less than half a pint.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication.

ILIFFE & SONS LTD.

A Question of Sale.

? I took my motor cycle to a garage for repairs, when the proprietor asked me if I would sell it, which I consented to do. He could not pay me at the time, but agreed to do so in three days, time. I went for the money on the date mentioned, but he still had not got it, and asked me to call again in a fortnight. In the meantime I decided to keep the machine for my own use. When I told the proprietor he said I could not have it. He had the money to pay me, but I would not accept it. There was no deposit paid. Shall I be compelled to let him have the machine?—C.S.

There was a valid sale of the motor cycle. To make a sale binding, it is not necessary for there to be anything in writing when there has been part performance of the contract, and, in this case, there was part performance by reason of the motor cycle being handed over to the garage proprietor. The fact that payment was not made as promised would not nullify the sale, but would simply give you a right of action for the amount.

Dynamo Lighting.

? I am anxious to fit a dynamo lighting and self-starting set on to a Morgan, and want your advice on the connections. I have a twelve volt twenty ampere dynamo with ring oiling bearings, and intend driving this from the flywheel, and fitting an accumulator. Should the accumulator be fitted in parallel or series to keep the lights constant? I have an automatic cut-out to stop back charge from the accumulator if speed gets too low. My idea is to light the lamps permanently from the accumulator and just let the dynamo keep the accumulator fully charged.—T.W.E.B.

The accumulator must be fitted in parallel. We are not sure from your query whether the dynamo is one made for car lighting, and therefore with some means of automatically regulating the output so as to avoid excessive current at high speeds, or if it is an ordinary shunt-wound machine. If it is the latter you will not be able to keep it charging and the lights switched on at the same time, as the variation in voltage would be too great and would burn out the lamps. You could, however, manage to work it so as to charge the accumulator and then use the accumulator independently for the lights, and, from the last sentence in your letter, we think this is your intention. In your first sentence you mention a self-starter; we presume you intend to use a separate motor for this purpose. It would be no good trying to use this dynamo as a motor for starting.

RECOMMENDED ROUTES.

NEWCASTLE TO GLASGOW.—D. McQ.

Newcastle, Ponteland, Otterburn, Carterbar, Jedburgh, St. Boswell, Melrose, Innerleithen, Peebles, Biggar, Lanark, Crawford, Hamilton, Glasgow. Approximately 145 miles.

CONGLETON TO DURHAM.—A.E.F.

Congleton, Buxton, Bakewell, Chesterfield, Barlborough, Worksop, Doncaster, Ferrybridge, Aberford, Wetherby, Boroughbridge, Leeming Lane, Scotch Corner, West Auckland, Spennymoor, Durham. This avoids all big towns.

STAPLE HILL TO CANTERBURY.—H.L.

Staple Hill, Marshfield, Chippenham, Calne, Marlborough, Hungerford, Newbury, Kingsclere, Basingstoke, Odiham, Farnham, Hog's Back, Guildford, Shalford, Shere, Dorking, Reigate, Redhill, Oxted, Westerham, Riverhead, Wrotham, Maidstone, Lenham, Charing, Canterbury.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—First 12 words or less 2/-, and 2d. for every additional word. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to **ILIFFE & SONS Ltd., and crossed & Co.**

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge, which must include the words Box 000, c/o "The Motor Cycle." Only the number will appear in the advertisement. All replies should be addressed No. 000, c/o "Motor Cycle," 20, Tudor Street, E.C.4.

DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

The Removal of War-time Restrictions.

1.—Petrol.

NOW that we are living once more under "Peace" conditions, it is becoming more and more obvious that the entire removal of those restrictions upon motoring and motor cycling, which were accepted loyally as unavoidable during the war, is somewhat overdue. Various ameliorations have already been made, and for this we are grateful. It is no longer necessary to possess a special permit before one is allowed to take a motor cycle on the road at all. The petrol regulations were amended as the supplies became greater, first by the granting of much larger allowances to every applicant and, secondly, by the permission to purchase the petrol, for which the preliminary tax of 6d. had been paid, in *any* month instead of only in the *specified* month as hitherto. Both these concessions were welcomed as valuable and convenient, and we are now expecting the final demise of the Petrol Control Department, and with it, we hope, the removal of the 6d. a gallon tax to which we have just alluded.

As reported in our columns last week, the Royal Automobile Club has already approached the Government on this matter, its Parliamentary Committee having pointed out to the Secretary of the Treasury the urgent need for the immediate withdrawal of this war tax. The Automobile Association and Motor Union has also taken a similar line of action and has elicited the reply that, while the Treasury does not propose to tax benzole, the tax on petrol cannot be dealt with before the consideration of the annual Budget.

2.—Lighting.

We have already expressed our opinion on the matter of red rear lights on cycles (including, of course, motor cycles), and have but little to add to what we have already said. We are glad to note that this regulation is to be retained in spite

of all that has been so furiously urged against it, but if the authorities decided to allow the use of a really good reflex lamp in place of a live light, we should have no objection to make. We would again point out, however, that the absence of rear lights on something like half the pedal cycles seen on the road, together with the extreme inadequacy of their head lights, robs the regulation of nearly its whole advantage. When one is expecting both front and rear lights on every vehicle, the absence of lights on a road should mean that the road is clear of wheeled traffic—the presence of an unlighted cycle is then more disconcerting than if no rear light regulation were in existence.

The screening of head lights has been largely modified, and motorists are now permitted to carry quite adequate lights, but lately—in fact, almost ever since the Armistice was signed in November last—we have seen motorists on the road who disregard the modified regulations in the most *glaring* manner. In fact, only last week a car passed us which not only lit up the whole countryside with its head lights, but exhibited a bright white light to the rear.

It is quite obvious that those who cavil at and disobey the rear light rule are largely instrumental in forcing these glaring head lights upon car drivers, but we notice, with some amusement, that complaints of bright head lights are now emanating from the same quarter whence the complaints lately arose.

We would urge the police to be more active with regard to these infringements of the law, for they are both a real nuisance to law-abiding people. We do not wish that a cyclist whose rear light is jerked out by a piece of bad road should be treated severely, but a man with no rear light at all should certainly be taught that laws are meant to be obeyed.

One thing more. Surely during the months April-September inclusive, lighting-up time might be as it was before the war, viz., from one hour after sunset to one hour before sunrise.

A 250 MILES RIDE IN THE HOLY LAND.

Experiences of Two Despatch Riders on a Journey from Damascus to Horns.

TO many despatch riders their life in foreign lands will form perhaps the most interesting of their experiences. More particularly does this apply to those whose lot it has been to visit warmer and yet fairly civilised countries, where the bugbears of motor cycling—mud, and war-wracked roads—are unknown. Many will, therefore, envy Corporal Gurney Grice and another D.R. (whose experiences are here recounted) their two hundred and fifty mile ride through picturesque Palestine. Rising early is a pleasure in such a climate, and at 8.30 one morning they set off from Damascus on the first stage of their journey, to a little town called Zahle, perched on the eastern side of the Lebanon Range. The roads must have been fairly good for them to average 25 m.p.h., which they did, arriving in time for early lunch. From Zahle the road led up the mountain side in an interminable zigzag of hairpin bends of no slight gradient, crossing and recrossing the railway, which was provided with a toothed centre rail to enable the engines to ascend at all. The summit is 5,050 feet above sea level, so that the view in that glorious atmosphere must have been worth seeing. From this point the road fell at a moderate gradient for twenty-five miles. During the descent the engine was used in some parts as a brake. Away in the valley the red-tiled roofs of the scattered groups of houses, nestling under the shelter of the mountains, gleamed in the sunshine. The road, too, was bordered by numbers of these little villages, well built, and quite modern, which were populated by Arabs or Lebanese.

A Modernised Town.

The arrival at Beyrout, with its well-made roads and electric trains, was a return to civilisation. Another asset of civilisation, speed limits, was apparently absent, as they romped into the town at 30 m.p.h., having completed the hundred miles from Damascus in just over four hours. Deciding to stay the night here, the D.R.'s looked up some friends, and billeted their machines. The evening was spent in looking round the old town, which, under German rule, had been in the throes of a famine, still reflected in the pinched and starved appearance of even the well-to-do.

Early next morning the machines were replenished with oil and petrol, and after strolling round the town for a time and partaking of various Eastern delicacies and a bottle of wine, a start was made at 11.30 for the town of Tripoli, where it was intended to stay the night. The

One of the D.R.'s—Cpl. Gurney Grice, R.E.

first stop was at the quaint little village of Jujunich—a place devoid of restaurants or any public eating places. However, a stray table and two chairs were discovered and commandeered, and preparations made for a meal. The victuals soon caused a crowd to assemble, and the natives were much attracted by a tin of jam, which they unsuccessfully endeavoured to purchase. Pushing on again, the enjoyment of the ride for the next few miles was marred by tyre trouble. This made it impossible to reach Tripoli before dark, so it was decided to stop at the next town *en route*. This proved to be Batroun, a picturesque little place, a jumble of red-tiled roofs, but civilisation was represented by "The Palace Hotel"—accommodation at five piastres (1s.) a night. Helping themselves to someone's door, the riders used it as a ramp to run their machines into a shop underneath the hotel. Washing was a most trying ceremony. A small Arab boy poured water from a bowl, and this was splashed on to the face with the hands, previously soaped. After an evening spent mainly in testing the edible qualities of the local fruit, a return to the hotel was made. The room which had been allotted to the motor cyclists was fairly clean, except for one minor discomfort incidental to the hot countries! As no illumination was provided by the management, an acetylene light was fixed up with a generator off one of the machines. This phenomenon attracted some other residents of the hotel to the room, and, as everyone had plenty to say, an enjoyable time was spent.

The hotel breakfast consisted of bully beef, onions, tomatoes, and maize bread, and at 10.30 a fresh start was made amidst a crowd of curious natives and others. The road for some distance was cut in the side of the cliffs overhanging the sea, and tunnelled through the rock in places. The surrounding country was well wooded,

and the Lebanon mountains, reaching almost to the sea, made a picturesque background.

Oranges, grapes, and pomegranates were obtained at many of the small villages scattered along the roads.

The End of a Perfect Ride.

Two more punctures caused some delay, but Tripoli was reached soon after one o'clock. The town was rather dirty, and the only hotel which could be discovered was not too inviting, so the riders slept in the open by a convoy of lorries which happened to be there.

The journey was completed by a seventy-mile run the next day to Horns—150 miles from Beyrout. Horns is a miserable sort of place, so the D.R.'s did not find much there of interest, except some boxes of Verey lights and Roman candles, with which they celebrated Peace.

CHINA AND THE MOTOR CYCLE.

IT may seem absurd on the face of it to advance the claims of China as a country likely to be interested in motor cycles, especially as British organisation in our Dominions is not yet perfect. It is significant to learn, however, that Dr. Chao-Hsin-Chu, B.C.S., M.A., Consul-General of the Republic of China, was a recent visitor to the Hendee Manufacturing Co. There he expressed views on the tremendous advance his country is making, and advised business men to establish trade relations with Chinese merchants direct rather than through Japanese channels. Many thousands of motor cars are now being imported into China, and sooner or later motor cycles will be common in the big towns. Who will be the pioneers, the Britisher or the American?

Automatic Carburetters.

READERS on the lookout for an automatic motor cycle carburetter should not forget the Claudel-Hobson. I know S. F. Edge defined an automatic as a device which gave an incorrect mixture at all speeds, and I dare not quarrel with him, for my Claudel is not economical. But it is a workable one-lever proposition. It is quite the surest starter I have ever tried, and it will run a flat twin engine from as slow a tick as one can hope for in this vale of tears up to over 3,000 r.p.m. on one setting with an acceleration which I have only excelled on a Henderson. On the eve of the war, I was about to try out an Everest, of which I had heard as another sound one-lever notion.

Wanted, a British Four-cylinder.

THERE are plenty of rumours, of course, but actual evidence that any British four-cylinder motor cycle is going into production is hard to come by. I saw more than one during the war, but they were frankly experimental, and seem to have been dropped. On the question of policy I have two remarks to make. The first is that until sound four-wheeled cycle cars come along, lots of folk will pay very high prices for a sidecar outfit *de luxe*—witness the popularity of the big Clynos, Enfields, Matchless, and many Americans. A good four has the best V twin whacked to the wide, and if any designer disbelieves in the cycle car, the four is his obvious line. In the second place, the 1914 Henderson satisfied me that the four has very special fascinations as a solo mount, both for luxurious travel on rational lines, and as a hogbus.

Incorrigible.

WHILST I am orating about cycle cars, I must revive an old heresy of mine and say that modern belts have never received full justice. It is perfectly astonishing what present day belts will stand, provided they are big enough and are given sound joints. Over and over again I have eradicated belt troubles by fitting a rin. in lieu of a $\frac{3}{4}$ in. or resorting to a similar trifling increase in contact area. There are limits to this process on solo mounts because a very stiff belt will not hug a very small pulley affectionately. But on a cycle car the load is divided between two belts, the belt line is not particular to an inch or two, and you can use a front pulley of walloping diameter if desired. The obvious solution of jointing a cycle car belt has not been tried so far as I know. The three commonest belt troubles are fastener mishaps, stretch, and slip. On a cycle car you can dodge fastener troubles by manufacturing endless belts: you can cure stretch with a turnbuckle on a radius rod by spacing out the pulley centres instead of getting out guillotine, punch, etc.; as you are compelled to do on a bicycle for dread of raising the gear; while slip is practically unknown with rubber

belts which are up to their load and have rational pulleys and pulley centres. Of course, if the cycle car is going to weigh 10 cwt., belts are probably an absurdity; but the Morgan originally weighed no more than $2\frac{1}{4}$ cwt., and, after four and a half years of featherweight engineering, I do not see why a pretty capacious four-wheeler need tip the beam at more than 5 cwt. If I were a cycle car designer, instead of a paltry, blithering, penny-a-liner, I should try out modern belts on the above lines, and bribe Messrs. Ormerod to make up a few dozen feet of their patent Watawata belting in rubbered canvas core instead of leather; it hugs a pulley better than any solid belt can, and I have often wondered why it has only appeared in the leather type.

Two Unconventional Pedals.

I SEE one of our readers is anxious to try an accelerator pedal as an auxiliary to the standard handle-bar lever. I carried out this experiment in an idle moment some years ago, but found it of no particular interest. If it possessed any merit it was in sudden deceleration. The handle-bar lever is seldom within easy reach of a normal finger when the throttle is fully opened. Thus it was often a convenience to leave the handle in minimum position and begin a speed burst solely on pedal control; when an emergency developed or a slow down was desired the pedal was released. Still the advantage was much too trivial to justify the complication. On the other hand, I rather liked an auxiliary pedal valve lifter with which I have experimented more than once. It is conceivable that a pedal compression release, with rather a more liberal leak than the standard valve lifter affords, might be worth consideration. It was very useful for wheeling the machine in pre-clutch days, and provides a pleasant form of coasting.

A Leakproof Petrol Tap.

WE all dwelt under the illusion that our petrol systems were leakproof until the Connaught people brought our their petrol two-stroke. Other makers followed suit, and we began to notice that the average privately-owned petrol baby was freely smeared with a greenery-yallery ooze over a large zone radiating round the petrol pipe and carburetter. The more fastidious of us tested our pump-oiled four-strokes by staining the fuel with a little oil, and then began a series of frenzied tap grindings. But unless one was lucky, these small taps proved incorrigible, and we gradually resigned ourselves to wasting a percentage of our precious fuel at so much per gallon. Then the war came along and the minutest petrol leak in aeroplane installations caused pilots to do rapid-fire profanity, ask emmas to be crimed, Governments to wax hectic, and many lovable youths to go west what time the tracer bullet streaked through the leakage area, or a mild crash dipped a redhot exhaust pipe

Occasional Comments.—

in the ooze. Then Benton and Stone invented a new positively petrol-proof tap with a cork seating. I s'pose we're to have it on our peace model 'buses, eh! what?

Pressure Lubrication.

AS several correspondents have recently clamoured for pressure oiling of motor cycle engines, it needs to be stated that there are two formidable arguments against applying this system. The first is financial, the second prudential. From a designer's standpoint, it is the easiest thing in the world to force a stream of oil through hollow shafts, but you can't do it as cheaply as you can employ flywheel "churn" to fling oil into the ends of bushes; and when all is said and done, the best motor cycle has to be sold in keen competition. Secondly, the pump and splash system is as simple and reliable as a system can be. But the adoption of forced oiling would import grave possibilities of trouble. Such a system includes a maze of small-bore oilways, and a single decent-sized fragment of dirt at various crucial points would block the circuit, arrest the lubrication, and lead to a seizure. Can we trust even 90% of our riders to observe the precautions essential to cleanliness? Are all motor cycle lubricants sold in a perfectly clean condition? How do riders behave when their requests for gratis repairs are met with an accusation of "under-lubrication by the user?" Do we wish to drive half our manufacturers into lunatic asylums? Nobody but the correspondence section of a works office knows what idiots some users still are.

Rear Lights or Reflex Mirrors?

VOICING what is merely a personal opinion, I hope the country is too sane to return to an illogical law, whereby only those vehicles which were seldom overtaken had to carry rear lamps. Cycles, being unobtrusive and silent, are *par excellence* the vehicles for which rear warnings at night are logically indispensable. If a 3-ton lorry were excused a rear light, it looms so large and makes such a dust and noise and smell that it could hardly be rammed unless it stopped its engine and sat under some trees in a very narrow road in a thick fog. As universal rear lamps avert even this mild and improbable peril, they are ideally desirable. On the other hand, rear lamps are an abominable nuisance. On a car they are of the oil or electric variety: if oil, you light them and drive away—when the flame promptly rises, fills the lamp with pendulous carbon, suffocates itself, and lands you in the police courts; if electric, they hop off their brackets and trail along the road till the flex chafes through—in this case you pay your fine plus two guineas for a new lamp. On a motor cycle, the tail lamp is usually acetylene: you nip the gas tube unconsciously with your thigh, or the burner of the front lamp carbons up, and you pinch the rear lamp burner as a spare. On a push bicycle you have to pay from 10s. to 15s. for a sound tail lamp, which you can probably ill afford. So the only peaceable solution, in my opinion, is for all vehicles to carry ruby reflex mirrors: the good ones are as efficient as red lamps, and free from all their disadvantages, whilst the Government can easily fix a suitable standard of efficiency.

A Privately Built Three-wheeler.

IT is extremely difficult to design a small three-wheeler if it is to look well on the road—a point which many professional designers appreciate. However, a Middlesex reader appears to have been fairly successful in producing a runabout approximating to the sidecar in size, weight, and appearance.

Built in spare time during the past three years by Mr. J. A. Payne, of Hayes, the little machine illustrated is a long way ahead of most amateur efforts; in fact, we have seen many marketed vehicles of this type which, on the score of finish and appearance, do not compare favourably with it.

The track of the machine is 4ft. and the wheelbase 5ft., while the power unit is a 6 h.p. twin Rex engine with overhead inlets, which is placed across the frame and is started by means of a handle in front. Five forward speeds and a reverse are obtained by a fric-

tion disc immediately behind the engine, the final drive being by 1½in. Whittle belt from an adjustable pulley. The steering is by rack and pinion.

The body is constructed of aluminium on ash framing, the rear wheel cover being hinged to facilitate tyre repair, etc. Tanks for three gallons of petrol and two quarts of oil are arranged under the scuttle dash.

Personally, we think it somewhat daring for an amateur constructor to embody friction drive, as this type of transmission does not, as a rule, give the most satisfactory service unless installed by experts in this particular line. Mr. Payne may give us particulars of his ex-

perience in this direction a little later, which should prove of great interest, as the friction transmission provides the most simple form of gear change for vehicles of this type. The final belt drive should be fairly satisfactory if the small pulley is not too small.

A RUNABOUT WITH ALUMINIUM BODY.

A "home made" cycle car built by Mr. J. A. Payne, Hayes, and fitted with a 1911 pattern 5-6 h.p. Rex engine. Friction discs and a Whittle belt are employed.

A BATCH OF PATENTS

It is, of course, too early for us to expect specifications of all the designers' post-war notions, but a batch of some two dozen patents now before me shows that brains are being profitably expended on some of our minor needs. Half a dozen stand to the credit of Mr. G. E. Rigby, who is responsible for the Royal Ruby.

Rigby's patent chain cover. Patent No. 121,371. 28/12/17.

He is out for leaf springing fore and aft, and has taken to heart the complaints which riders make about chain adjustment. For example, the average rear chain is difficult to expose, since its case must be rigidly mounted if rattles are to be avoided. So Mr. Rigby proposes to secure a skeleton cage of strip metal or stiff wire firmly to the machine, and to slip a quick-detachable cover over the cage. Or again, a gear box is often hung from four studs threaded through slots in

Rigby's gear box adjustment. Patent No. 121,099. 2/8/18.

a bracket, and secured by nuts above the bracket. Chain adjustment is performed by slacking four more or less accessible nuts and clamping the gear box to and fro with a mallet, and as the bolts must be a free fit in the slots alignment is often lost. Under Mr. Rigby's patent the rider tightens his chain by slacking one nut and tightening another, having first loosened the nuts of the clamping stud, whilst alignment is infallibly maintained.

Monie's patent. No. 118,331. 25/8/17.

Give me a Scotchman for thoroughness. The picture of Mr. M. M. Monie's rear wheel puncture preventer is self-explanatory. He naively states in his claim that the idea was inspired by sustaining forty-seven punctures in 11,000 miles. After fitting the protector he rode 10,500 miles and "over 25,000

nails" (to quote from the patent specification) without punctures. But what about the dust, Mr. Monie?

Mr. C. T. B. Sangster has a real novelty in disc wheels. He anchors the off and near side discs to each other and to the wheel by means of the meat hook clips, using radial wire spokes instead of the tangent pattern. Then he fixes the sprocket or belt pulley directly to one of the discs, so that a disc takes the drive. I cannot imagine one of these discs becoming loose, which is more than can be said of most types.

Sangster's wheel discs. Patent No. 111,428. 4/5/17.

The New Hudson Co. have a new gadget for fitting brake or clutch pedals on spring footboards without straining the Bowden wire connections. This is obviously better than confronting the driver with a footrest which keeps varying its position in relation to the pedals, and should be valuable on "baby" machines, where the weight of a fully sprung frame is prohibitive. The Clyno designers have two patents of interest, both relating to detail. As outlined above, Mr. Rigby, of Royal Ruby fame, considers that a chain case should be (1) quickly detachable and (2) rattleproof.

The Chain Case Problem.

The Clyno thinkers are rank cynics on this matter. They imply that detachability and silence are incompatible ideals, and suggest a rider, "What about oil leaks?" M.G.C. experience and Scottish trials have made them pessimistic, and where chain cases are concerned they agree with the philosopher who told us when we found a true friend to grapple him to our soul with links of steel. So

The Clyno gear case fixing. Patent No. 117,763. 21/11/17.

their chain case clip goes as follows: A hollow cone split by sawcuts is brazed to each side of the chain stay. A hollow half cone is formed on both sides of each half of the chain case. These pairs of half-

cones fit snugly over the cones on the stays. Hollow conical caps slip over the assemblies, and a threaded bolt is then passed through the lot, and drawn up tightly with a nut. I do not remember Frank Smith losing a chain case in a big trial, but he has evidently encountered dirty work at the cross roads some time or other.

Mr. W. H. Osborne is specially interested in front forks. He stamps or presses each side of a trussed fork of very pleasing appearance from one piece of metal, as indicated in the side view and the section. This should be as strong as it is handsome. Moreover, he recognises that, though a fork of the Druid type is devoid of lateral sway when new, it may easily develop a degree of side rock in prolonged use, since the inner face of each link end rubs against the boss through which the spindle is threaded. So he proposes to insert adjustable collars or bushes at one end of each spindle bearing, whereby wear can be taken up, and the fork kept laterally steady.

Osborne's sheet metal fork. Patent No. 118,920. 22/9/17.

Osborne's improvements in linked forks. Patent No. 119,889. 12/9/17.

I have been led to believe by artists, interneers, and others that Holland is a very flat country, but now—on purely circumstantial evidence, mind you—I advise the A.C.U. to hold the next Six Days there. The Dutch gradients are terrific. How do I make that out? Very simply. Mr. Cornelis Willem Kuijper points out that if the transmission of a motor cycle brake snaps or becomes otherwise deranged, you cannot put the brake on. In his opinion it is far better that such a fracture should make it impossible to take the brake off. So he mounts a drum on the hub, and slips a multi-twist

A Batch of Patents.—

helical spring of immense power inside it. A spring-catch control lever or pedal is provided, which normally holds the spring compressed inside the drum; on releasing the control, the spring expands with a bang against the interior of the drum; and of course if the Bowden con-

The James gear box and crank case layout.
Patent No. 121,231. 25/2/18.

nection snaps or a nut falls off a coupling rod, the same occurs—the brake is hard in, pending repairs. Frankly, I could not drive a machine fitted with the Willem Kuiper brake: the thought of its suddenly going hard on when I was doing sixty would make me wake in a cold sweat o' nights. Hold hard! Is this our old friend Billy Cooper pulling our legs, *more suo*? Does anybody know if he has been interned?

More power to the James Co. It has dawned on them that high-powered machines are chiefly used with sidecars, and that the modern sidecar, being usually a cross between an Admiralty buoy, a Canadian canoe, and a Sedan chair, is apt to obstruct accessibility to

the left-hand side of the motor cycle. So they are redesigning their cycles with this thought in mind. Not content with mounting the more vulnerable items, such as carburettors and contact breakers, on the right—a simple trick which has already occurred to commoner minds than theirs—they have envisaged a true ideal, *i.e.*, that if you tilt the bicycle over towards the right, all its inside should slide out. They have not fully attained this height in their present patent, but they are climbing towards it. They construct their gear box and crank case in the likeness of cupboards: you just take off the right-hand end plates and remove their innards. Very nice, too!

A Swiss firm, the Conder Manufacturing Co., have patented a two-speed gear which looks unusually foolproof on paper. The gear box is of the two-speed dog clutch type, so familiar on the earlier Douglas machines. The countershaft

The band brakes on a Swiss gear box.
Patent No. 114,413. 14/12/17.

sprocket, driven by the engine, is provided with a drum, on which are two clutches of the brake band variety. These two clutches are so coupled to the gear shifting mechanism that one of them is tightened when a gear is engaged, and that both are free when the gears are in neutral. Thus the movement of a

A. T. Collier's gear box. Patent
No. 121,406. 22/2/18.

single lever controls the clutches and the gears. This is the first foolproof dog-clutch gear I have encountered. Its value in practice will obviously depend on the ease with which the clutches can be adjusted and their durability. A naked external band clutch of small area does not look too promising for motor cycle purposes at first sight.

Mr. A. T. Collier's gear is of the bevel pinion epicyclic type, but, unlike its predecessor, the Nala hub, provides three ratios, there being two sun wheels engaging planet pinions of different diameters, the gear revolving solid on top. The Nala hub proved reliable in use, but was heavy.

B.H.D.

TECHNICAL ABBREVIATIONS.

Notes on some Little Things that Mystify the Novice.

THERE are many things that puzzle the novice, when first entering the ranks of potential motor cyclists by reading *The Motor Cycle*, and not the least among them are the technical abbreviations which are frequently mentioned in the context and advertisements. There are hundreds of potential newcomers to the pastime who know little of mechanics, and it is for their benefit that this page is penned in the form of a glossary of terms most commonly used.

Flat Twin.—Now almost generally used as the type name of the horizontally-opposed two-cylinder engine.

Cyl.—Cylinder.

O.B. Sidecar.—Coachbuilt.

K.S.—Kick-starter—a pedal for starting the engine.

h.b.c.—Handle-bar control.

F.B.—Footboards.

F.R.—Footrests.

Combination.—A trade designation of a sidecar outfit.

Amp.-hour.—An electrical term denoting the capacity of an accumulator.

Single-speed.—One gear ratio only.

Two-speed.—Two gear ratios (and so on).

Hub Gear.—A gear contained in rear hub, usually of the epicyclic type.

Planetary Gears.—Epicyclic.

c.c.—Cubic centimetres—usually used to denote the capacity of the space swept by the piston, or pistons, of an engine.

Bore.—The diameter of the cylinder.

Stroke.—The length of travel of the piston.

mm.—Millimetre. The metric system is used in most engine dimensions. Also by tyre makers in connection with tyres made to suit car type rims.

Revs.—An abbreviation for revolutions.

Revving.—A coined word, meaning revving.

Clutch.—A device by which the engine is gradually connected up to the driving mechanism of the road wheel. Also called a free engine.

Mag.—Short for magneto.

a.c.—Air-cooled.

w.c.—Water-cooled.

a.o.i.v.—Automatically operated inlet valve, or atmospheric valve—a valve opened by vacuum before it or pressure behind it.

m.o.i.v.—Mechanically operated inlet valve.

m.p.g.—Miles per gallon.

m.p.h.—Miles per hour.

r.p.m.—Revolutions per minute.

f.e.—An abbreviation used chiefly by advertisers in the miscellaneous columns to denote that a machine is fitted with a clutch (free engine).

h.p.—Horse-power.

b.h.p.—Brake horse-power. The actual power developed on the "brake," *i.e.*, the testing machine.

i.h.p.—The horse-power shown by an indicator during tests.

n.h.p.—Nominal horse-power, *i.e.*, the power given by the manufacturers as approximate.

Countershaft.—Denotes that a machine is fitted with a gear box between the engine and road wheel.

T.T.—Tourist Trophy. Sometimes used to signify type of machine, *i.e.*, a semi-racing mount on the lines of the machines used in the Tourist Trophy Races.

Two-stroke.—Sometimes erroneously termed two-cycle. An engine completing its cycle of operations in two strokes of the piston—one up and one down. Usually a valveless engine.

Four-stroke.—Sometimes erroneously termed four-cycle. An engine completing its cycle of operations in four strokes of the piston—induction, compression, power, exhaust.

Historic Fact.

THE first British Motor Cycle used in the war by the French and Italian armies was the TRIUMPH, but the British Armies soon insisted that the entire output of the famous TRIUMPH Motor Cycles should be reserved to them and them alone.

This is the finest tribute that can be paid to the production of any manufacturer, and affords incontrovertible proof of the sterling merits of

TRIUMPH

Motor Cycles.

The 1919 Models, which are exact replicas of those which have proved their efficiency in every respect in all the war zones, may now be obtained at the following prices :

4 h.p. Type H.	£87
2½ h.p. Type L.W.	£54

TRIUMPH CYCLE CO., LTD.,
COVENTRY.

London: 218, Great Portland Street, W.1.
Also at Leeds, Manchester, and Glasgow.
(The Company has nearly 2,000 Agents in the British Isles to attend to the wishes and needs of Motor Cyc'ists.)

ANY means of getting from one place to another by road should provide comfort, interest, and speed at a reasonable cost, without the introduction of mechanism which is delicate or difficult to understand.

The G.N., departing from the conventional in many respects, does so with excellent reason; it was originated by H. R. Godfrey and A. G. F. Nash over ten years ago, and is the outcome of their experience and continued progress in design; its simplicity and lightness make it a vehicle of high-performance, with economy in both first cost and running.

Reminiscences by (Rev.) F. J. Ashley, formerly Chaplain and Capt. S.A.M.C.C.

The first part of the story—published last week—deals with the journey from Voi to Moschi, and leaves the column on their ninety miles' journey to Lol Kisale.

THE Colonel sent an officer ahead with despatches, and I went with him for company. The first part of the seventy miles' ride was along the side of the mountain range, with the cliff for a wall on the left and a precipice on the right, and it was seldom possible to see far ahead. The officer led, I followed, and three of his men rode behind me. He set a rattling pace, and I did not like it. What I feared came to pass. On rounding a bend I saw at a glance that the wall had fallen down, leaving a narrow space on the edge in which the leader was wedged. I was going a good twenty, if not more; jammed on the brake and stood on the pedal, skidded, and in a flash was over the edge. Fortunately a bush some twenty feet below pulled me up, and as the cliff was a little out of the perpendicular we were able to drag the machine up, and found it had no damage beyond two nuts loosened, while I had a few bruises. After that we travelled under brake control. The remaining ten miles into Kondoa were a nightmare struggle through sand as soft and deep as that on a seashore.

Attacked by Bees.

Some little riding was done between the kopje we occupied later and the town, a distance of about $2\frac{1}{2}$ miles. I was threading my way back to the kopje one day when I suddenly came on a machine lying overturned on the edge of a donga. It was in full view of the kopje, and only four hundred yards distant from it. I could not understand it, for it was rank heresy to leave a machine thus, and if it had been an accident it would have been observed. I saw several figures moving about the kopje. I shouted; there was no answer. I called the number of the machine! still silence; but, just as I was going to look over the edge of the donga, there came a loud "Buzz-z-z," and the next moment my machine was lying in com-

pany with the other and I could not be seen for dust as I legged it down the track, slapping at every sting I received. A hive in a neighbouring baobab tree had been robbed of its honey, and the bees were waiting for anyone who came along. I had to get a mosquito net and put two pairs of socks over my hands before I could go back for my machine, and the bees covered my net in a cloud till I left the tree well behind.

A Crash!

One of our Q.M. sergeants had not long arrived and had a curious tale to tell. He with another man set out from Moschi after the corps, and some twenty miles out missed the road and went off down a native track. After several miles the track seemed to peter out, and they knew then they were wrong. Unfortunately this man developed malaria and was not fit to go on, having become partially delirious.

The next morning the poor fellow was unable to move, so the Q.M.S. started on foot along a small path which, according to the lie of the country, would strike the Aruscha-Moschi road. He reached it after a tramp of some five hours, and was fortunate enough to meet a bullock waggon on transport duty. After getting refreshment he started back with water bottles full and reached his camp at night. The next morning the sufferer was able to travel, and they picked their way back and got on to the right road. There was a comical finish. The invalid was still feverish and rode erratically with the Q.M.S. behind him to pick him up when he fell. Suddenly a green tent came into view surrounded by canvas chairs, washstands, and other impedimenta of officers not belonging to fighting units. To his horror the Q.M.S. saw the other swerve once or twice and then head straight through the grass for the tent. He crashed into it, bringing everything down in ruins amidst the sound of decanters and bottles falling and volleys of oaths. The

From Kilimanjaro to Nyasa.—

Q.M.S. waited for no more but opened his throttle fully and flew past to a safe distance and then pulled up. Presently the swaying rider appeared.

"What did they say?" demanded the Q.M.S.

"Oh! they swore a good bit," muttered the other with dull eyes and a flushed face.

"And what did *you* say?"

"Oh! I asked them if this was the way to Lol Kisale!"

We had now developed a strong respect and affection for our mounts, which seemed able to stand any amount of rough usage and hard knocks. In this connection a motor cyclist riding up a path alongside a donga with an 80 lb. drum of oil on his carrier skidded over the edge and dropped fifteen feet. Even the carrier did not give way. The carriers, though, were the weak parts of the machines, but they were never designed to be subjected to such work as we were forced to give them, since we had to travel self-contained.

section and he, tired of the eternal flour and water "damper," determined to make some "fat cookies"—a South African delicacy of flour cooked in fat. The fat they used was Mobiloil A!

"But didn't it half kill you?"

"It gave us heartburn for a bit, sir!"

And I have memories of Kilossa on that score. The doc. and I had five ducks' eggs given to us by a friendly native, and we handed them over to our orderlies to cook and then dreamed dreams. We hadn't had eggs, it seemed to us, for years.

"It's ready, sir! We've made an omelette."

And they had, but it was made with cocoanut oil! That was one of the most cruel disappointments I've ever had. The doc. stamped off beyond speech, but, eggs being eggs, I ate some of the omelette, and it was a week before I lost the taste of cocoanut oil.

Doctored Machines.

It was here a fault-finding competition was devised. Each platoon entered three men, and three machines

Natives embarking motor cycles on H.M.T. "Chancy Maples," Mbamba Bay, Lake Nyasa.

Riding under a hot sun, over such roads and carrying such loads, threw a great strain on the engine and gear box, but they stood it nobly. An officer told me when he returned from a trip back to Moschi that the roads were so badly ground into dust that a car travelling threw up a wave before its radiator like those from the bows of a steamer. On one stretch of seventy miles he never once got out of low gear, and in that space used a tank of oil. It seemed tall, but we did many similar things later. Perhaps the greatest expenditure was on spokes, the all-chain mounts being the greatest offenders. The adjutant told me, towards the end of the campaign, we had got through over a hundred gross of them. On reckoning it up I well believe it.

The humorous side of things was always to be seen. Even the short rations could not altogether depress the men. How desperate was our plight can be pictured by what my batman told me one day when I complimented him on his cooking. He said that his half-

were "doctored" by the mechanics. The Colonel's machine was one, and for a first trial the carburetter had water poured into it. When the first competitor was called from the hut he came forward, put his hand on the plug and gave a vigorous dig to the kick-starter to test the spark. To our surprise the engine started, and there was a roar of laughter during which the man retired thinking his leg had been badly pulled. The explanation was, of course, that the petrol flowed to the jet without entering the float chamber.

On another machine the brush at the end of the high-tension wire was removed, but that engine started, too, the spark jumping from the slip ring to the end of the wire which was fitted a little way into the opening to conceal the fault.

One man I know would have been glad of such a live mag., for he was discovered by the roadside bemoaning the fact that he could only get a spark from two points of his plug and not all three. He was a recent addition, I might add.

From Kilmanjaro to Nyasa.—

At Kidek one platoon rode into a force of 3,000 men waiting for our division, and when fire was opened upon them the leading men thought their engines were missing and backfiring, and only on glancing down and behind did they see the spurts of dust. They left their machines hurriedly enough then to get under cover. One of them said after that what worried him most was to lie there and see the petrol dripping from tank and jet, because petrol was so scarce that orders had been issued threatening severe penalties on any man wasting it.

The enemy were a little too confident, however. They captured two of our men escorting a ration party and threw their B.S.A.'s over a high bank down on to a rocky river bed, which happened to be dry. Natives reported their whereabouts, giving us in graphic pantomime the idea that they were smashed up. But through

experience we thought B.S.A.'s were not so easily smashed, and two cyclists were sent out carrying two more men pillion fashion. If they could be towed back the various uninjured parts would be useful as spares. The machines, however, came back under their own power.

Our last ride when we left the country, Kigonsera to Mbamba Bay, deserves a chapter to itself, and I cannot hope properly to describe it in less. Briefly, it was a "road" the engineers had not tackled, and we had only the native path through the Livingstone Range to follow. It was the rainy season, and we had to overcome mud, rocks, rivers with no bridges, and thick bush, taking three and a half days to do fifty miles. It was an epitome of all we had encountered except sand, and we were glad to walk over that to embark on the steamer that carried us down to Nyasaland.

IMPROVING A 7 h.p. TWIN.

Details of Some Minor Alterations which gave added Efficiency.

SOME considerable gain in convenience has been obtained by the owner of an Indian motor cycle, Mr. H. A. T. Stanton, A.M.I.E.E., of 4, Ainslie Street, Barrow, from the small yet effective alterations described. As these alterations refer to kick-starter and clutch mechanisms, possibly the ideas embodied therein may be of value to riders of other machines.

The kick-starter, chain wheel, engine sprocket, and chain were replaced by a new quadrant and sprocket, as shown in figs. 1, 2, and 3, giving a ratio of 4 to 1 between quadrant and sprocket in place of the previous ratio of 3.17 to 1. This increase in ratio enables the engine to be turned both further and quicker for a given kick, and, with the larger kick stroke obtainable with the new quadrant by hinging the footboard to drop clear (figs. 2 and 3), the engine starts at the first kick. The new sprocket has radial teeth arranged to fit the existing ones on the engine-shaft. It has a light spring in front which perfectly ensures engagement of these teeth when the sprocket is driven forward by the quadrant, and permits the latter to return to the "ready" position, when the sprocket is driven backwards.

Another point concerns the clutch, which the owner found somewhat difficult to adjust. When sufficiently tight it was never really free in the "out" position; and conversely when adjusted to be free it slipped on hills. A diagnosis showed the defect to be due to inadequate movement of the clutch pedal.

The near-side pedal, with its many connecting rods and levers, was therefore replaced by a new off-side pedal mounted close to the gear box, as in figs. 4 and 5. The clutch rod, which projects from the off-side of the gear box, was fitted with a chain wheel in place of the existing lever, and the new pedal connected directly to the chain wheel by a length of $\frac{1}{8}$ in. bicycle chain. This pedal was supported by a new bracket fixed to two existing engine bolts, and by means of a slot for one of these bolts the bracket can be swung to adjust the chain.

The writer wishes to say, in anticipation of these improvements appealing to riders of similar mounts, that no alterations whatever to any existing parts are involved, and that he is willing to supply the drawings to anyone desiring them.

(1) Kick-starter in normal (i.e., housed) position. (2) Kick-starter ready for use. (3) Starter in position at finish of kick stroke. (4) Clutch pedal in position. (5) Clutch pedal in the "out" position.

Times to Light Lamps.

GREENWICH TIME.

Mar. 6th	6.16 p.m.
" 8th	6.19 "
" 10th	6.23 "
" 12th	6.26 "

French Racing Track.

An immense motor racing track in the neighbourhood of Paris is proposed.

The 50 lb. Machine.

Our U.S. contemporary, *Motor Cycle and Bicycle Illustrated*, announces the new A.B.C. in the following headline: "Four Speeds—50 lb.—160 Miles per Hour."

Roads in the North.

A correspondent in Inverness asserts that the main north road has ruts so deep that the footboards of his machine were touching the edges as he proceeded along the road.

Speed Limits.

An agitation has been started in Toronto for the raising of the speed limits in the province of Ontario. The Provincial Legislature will be asked to increase the limit from 20 to 25 m.p.h. in the country, and from 15 to 20 m.p.h. in the cities.

Petrol.

There is apparently considerable delay in obtaining petrol licences by direct application to the P.C.D., so that motor cyclists are advised to send their particulars to one of the associations dealing with the question.

The Automobile Association, Farnham House, Whitcomb Street, London, W.C.2, has been able to arrange the issue of hundreds of licences within twenty-four hours to applicants, whether members of the Association or not.

The Industrial Reconstruction Council.

A conference on "Labour Conditions in Relation to Future Industrial Prosperity" will be held under the auspices of the Industrial Reconstruction Council on Tuesday, March 11th, at 6 p.m., in the Hall of the Institute of Journalists, 2 and 4, Tudor Street, E.C.4. The chair will be taken by Maj. the Hon. Waldorf Astor, M.P., and the opening address delivered by Capt. James O'Grady, M.P., secretary of the National Federation of General Workers. No tickets are necessary.

Summer Time.

The morning of Sunday, March 30th, will mark the commencement of Summer Time, which will continue until the night of Sunday-Monday, September 28-29.

Annual General Meeting of the A.C.U.

We have already stated that the annual general meeting of the A.C.U. is to be held at Birmingham. The date has been fixed for March 22nd, the meeting to take place in the afternoon at the Digbeth Institute.

"Rich Mixture."

We are in receipt of the Souvenir number of an excellent publication, entitled *Rich Mixture*, which is written and illustrated almost entirely by officers, N.C.O.'s, and men of the Home Mechanical Transport Depot, R.A.S.C. The profits on the sale of the Souvenir go to St. Dunstan's Home for the Blind.

Rich Mixture contains much that is interesting, and much that is amusing; its illustrations are clever, and the motor cyclist R.A.S.C. is not ignored. Most people think that the R.A.S.C. had a soft job at the Front, but many instances are given of the great dangers to which the men were constantly exposed.

Special Features.

A BATCH OF PATENTS.

250 MILES RIDE IN THE HOLY LAND.
1919 MODELS.

Priming Pipe Design.

A reader points out that his priming pipe had a deep curve in it, and, realising that the petrol lay in the loop and got stale, he shortened the pipe and made it run directly from the tap union to the compression tap. He now finds that the starting is much easier, as fresh petrol is injected every time.

After Many Days.

That the Germans have taken care of various mails they have captured is proved by a letter shown to us by Mr W. Carson, of Bayliss, Thomas and Co. (British Excelsior). It was posted in Copenhagen on December 9th, 1916, and arrived in England on January 21st, 1919. The envelope was opened and resealed by the German authorities, and also by the British Censor, who marked it "Part of a mail captured by the Germans and delayed."

The vogue of the three-wheeler of the Morgan type has not yet reached America, although the three-track passenger outfit illustrated has gained a limited popularity. The driver, however, is exposed to the weather with this outfit, which compares unfavourably on many points with the fully-equipped double-seated sidecar.

Second-hand Prices.

The second-hand market has apparently passed its zenith, and the average of the prices asked is becoming slightly less week by week. The following list gives the average of the prices advertised in *The Motor Cycle* of February 20th and 27th for second-hand machines:

	Previous to 1914.	1914 and 1915.	1916 and 1917.
A.J.S., 6 h.p.	—	—	£78
A.J.S., 2½ h.p.	—	£40	—
Allon, 2½ h.p.	—	£33	—
Bat, 6-8 h.p., and sidecar	—	£65	—
B.S.A., 4½ h.p., and sidecar	—	£55	£82
Calthorpe-J.A.P., 2½ h.p.	—	£30	£35
Campion, 4 h.p., and sidecar	—	£41	—
Douglas, 2½ h.p.	£21	£44	£55
Enfield, 6 h.p., and sidecar	—	£60	£100
H.-Davidson, 7-9 h.p.	—	—	£100
H.-Davidson, 7-9 h.p., and sidecar	—	£105	—
Indian, 7-9 h.p.	—	£50	—
Indian, 7-9 h.p., and sidecar	—	£70	—
Matchless, 6-8 h.p., and sidecar	—	£80	—
New Hudson, 3½ h.p.	—	£40	—
Norton, 3½ h.p.	—	£70	—
Rover, 3½ h.p.	£30	£45	—
Sunbeam, 3½ h.p., and sidecar	—	£75	£85
Triumph, 4 h.p., sidecar	—	£45	—
Triumph, 3½ h.p.	£25	—	—
Zenith 4 h.p., sidecar	—	£37	—

Government Reply to the A.A.

The Secretary of the Treasury, in replying to the representations of the A.A., urging the removal of the super-tax of 6d. per gallon on petrol, said:

"(1.) That while their Lordships have refrained from extending the Excise duty to benzole, they have no power to waive the Statutory requirements of the Finance Act, 1916, covering the issue of fuel licences and the payment of duty for ordinary motor spirit.

"(2.) That they are unable to deal with the matter in advance of the general consideration of the Budget requirements of the year."

The energetic Automobile Association is not satisfied with this reply, and will continue to agitate for the abolition of "control" of motor fuel, the necessity for which no longer obtains, and the super-tax of 6d., which was imposed purely as war-time expedient.

Benzole.

A new company is to be formed to undertake the distribution of benzole. This fact was announced at a meeting held in London the other day to inaugurate the newly formed National Benzole Association, which is an association of benzole producers. Many distinguished persons were present at the gathering, and the President, Mr. D. Milne Watson, who is also president of the Gaslight and Coke Co., took the chair.

Mr. E. S. Shrapnell-Smith stated that the Board of Customs and the Treasury do not intend to impose the sixpence a gallon tax on benzole at the moment. He also declared that the consent of the Treasury and Board of Customs had been obtained for trial on a large scale of a mixture of 75% alcohol and 25% benzole on motor omnibuses in the London area, which is a big step in the right direction for fostering the use of home-produced fuel.

The significant announcement that at present benzole could not be sold at a less cost than petrol was made by the chairman.

A useful suggestion was put forward by Mr. E. S. Shrapnell-Smith that the motor-ing organisations should participate in the capitalisation of the new distribution company.

THE DISPOSAL OF ARMY MOTOR CYCLES.

No definite plan has yet been decided upon by the authorities as to the ultimate disposal of the bulk of surplus Government motor vehicles.

Prospective buyers of ex-W.D. motor cycles are advised to apply to the Controller of Mechanical Transport Disposal Department, 1, Grosvenor Place, London, S.W.1.

As it is impossible to announce sales beforehand, those interested in the sales at Aldridges should write to Aldridges' Repository, St. Martin's Lane, W.C.2.

Tyres on Lightweights.

Most of the 1919 lightweights have 26×2½ in. tyres instead of 26×2 in., which, in view of the present condition of the roads, is a step in the right direction.

Olympia Motor Cycle Show.

The Olympia motor car show being announced to open on November 7th, it may be taken as practically certain that the motor cycle show will be held about a fortnight after November 15th—the date the car show finishes.

The 4 h.p. Blackburne.

The Blackburne motor bicycle, referred to in the issue of February 27th, fitted with an engine 85 mm. × 88 mm., 499 c.c., is to be known as the 4 h.p.

Owing to a typographical error the wheelbase was mentioned in our description as being 4ft. 1in., while it is actually 4ft. 11in.

A Flat Twin Auxiliary.

We understand that the Johnson auxiliary motor, which was described in a recent issue, will be made in England under licence from the American company. It is said that an English officer, who lately returned from the States, has secured the British rights. It will be recalled that this auxiliary engine is a 1½ h.p. flat twin two-stroke, embodying a magneto fly-wheel, from which current is also obtained for the lamps.

Empire Trade Commissioner.

The Association of British Motor and Allied Manufacturers has appointed Major R. E. Goddard as its Overseas commissioner for the purpose of conducting a tour of investigation of the markets of Australasia, India, and the East.

Auction Sale of Fifty Motor Cycles.

Fifty motor cycles, together with accessories, are advertised to be sold by auction on Friday, March 7th, by Harry Reeman, auctioneer, Colchester. The advertisement in a daily newspaper states the sale will take place owing to "the termination of Government contracts."

The War Tax on Petrol will go.

As announced in last week's issue, the 6d. per gallon war tax on petrol may be removed shortly. The R.A.C. has been moving vigorously in this matter for some time, while the A.A., too, has had a lengthy correspondence with the Board of Trade and H.M. Treasury. Now the Motor Legislation Committee, composed of officials of the various motoring organisations, has sent a resolution to the Chancellor of the Exchequer and the Financial Secretary of the Treasury.

A Ministry of Ways and Communications.

The proposed new Ministry of Ways and Communications, of which we have already spoken, is to be entrusted, it is suggested, with the control of railways, light railways, tramways, canals, roads, bridges, vehicular traffic regulations, and electric supply. Great opposition will be taken to the measure, for obviously the control of the roads should be a separate administration. *The Motor Cycle* and *The Autocar* and every motor organisation have strongly protested against the roads being controlled by a body of men whose main interests are in railways.

Mr. W. Joynson-Hicks, M.P., chairman of the Motor Legislation Committee, has forwarded to the Local Government Board a strong protest against any proposal which will place the roads under the same Ministry as railways and canals.

There are ample economical reasons against such a proposal, as the interests involved are in many cases quite opposed.

**THE FIRST WEEK IN MARCH.**

Contrary to the programme of the seasons, March came in "like a lamb," and many motor cyclists took advantage of the mild weather to picnic in the open.

Midland C. and A.C.

The motor cycle section sub-committee of the Midland Cycle and Athletic Club consists of Messrs. J. Webb, C. F. Dawes, Frank Whitworth, and R. H. Henderson, who will deal with the club's forthcoming sports meetings and motor cycle trials.

Woolwich, Plumstead, and District M.C.

As far as possible the 1914 fixture list will be carried out this year. An important non-stop trial is the 50 mile non-stop run to be held on April 6th, starting from Knockholt, Kent. Three prizes will be awarded, and entries will be received at the start, by the hon. secretary, Mr. F. J. Ellis, 3, Nightingale Place, Woolwich, S.E.18, from whom full particulars may be obtained.

Harrogate and District M.C.C.

This club has now been revived, and the old executive re-elected. The programme includes social events and competitions for motor cycles, light cars, and cycle cars. Special arrangements are made for visitors to the district, and reduced subscriptions for members resident outside a twenty-five mile radius. The hon. secretary is Mr. H. W. Fortune, St. James's Chambers, Cambridge Street, Harrogate.

Nottingham and District M.C.C.

This club has recently been re-organised, and many new members enrolled. A Challenge Trophy, value 100 guineas, has been offered by Mr. H. Bowden, of the Raleigh Cycle Co., Ltd., for which the competition will be open to all comers. The course will be a sporting one over parts of Nottinghamshire, Derbyshire, and Staffordshire. The Committee Meeting is to be held at the Welbeck Hotel, Nottingham, on the 7th inst., when it will be possibly decided to hold speed trials, on a road stretch that has already been selected.

The M.C.C.

Members of the M.C.C. are requested to read carefully the paragraphs relating to the M.C.C. in these columns, so that they may keep in touch with the club and its doings, and should necessity arise to communicate with the secretary, as the list of members and their addresses is undergoing revision.

The opening run will take place on April 6th to the Red Lion Hotel, Hatfield. Cold luncheon will be served there at 1 p.m. Those intending to be present at the lunch must send in their names at least a week beforehand to Mr. A. C. Armstrong, 7, Rosebery Avenue, London, E.C.1, as unless this is done places cannot be reserved for them.

Future Events.

Mar. 9.—N.M.C.F.U., Sheffield. Run to Hathersage.

Mar. 16.—N.M.C.F.U., Sheffield. Run to Blyth.

April 5.—Birmingham M.C.C. Opening Run.

April 6.—The M.C.C. Opening Run to Hatfield.

April 6.—Woolwich, Plumstead M.C. Non-stop Trial from Knockholt to Lamberhurst and Back.

April 13.—Liverpool M.C.C. Opening Run.

April 18.—Darlington B and M.C. Opening Run.

April 21.—Birmingham M.C.C. Easter Trials.

April 21.—Dublin M.C.C. Dunlop Cup Trial.

June 9.—Dublin M.C.C. Whit-Monday Trial.

June (end of).—Dublin M.C.C. Twenty-four Hours' Reliability Trial.

Aug. 2 and 4.—Dublin M.C.C. Two Days' Reliability Trial.

East Midland Centre A.C.U.

Several new clubs are being formed in the Nottingham area, due to the efforts of Mr. J. Simmonds, the hon. secretary, who will be pleased to hear from motor cyclists residing in Newark, Southwell, Mansfield, Worksop, Alfreton, Long Eaton, and Hucknall areas. His address is 10, Cranmer Street, Nottingham.

Birmingham M.C.C.

The Victory Cup open reliability trial for solo and passenger machines will be held on April 21st. The course will be 125 miles, and include several well-known test hills in the Midlands. There will be special conditions for low-power machines. The awards consist of three special silver cups: the Victory Cup for best performance by any machine; the Duke Cup for the second best performance; and the Evans Service Cup for the best performance by a member or ex-member (either sex) of H.M. Forces. In addition, there will be first and second-class awards, and, if sufficient entries, a special award for the best performance by a lady driver.

We shall be pleased to hear again from secretaries and others regarding existing and proposed clubs, their programmes, and any other interesting particulars. We are prepared to assist with advice and publicity those desirous of establishing clubs.

Coventry and Warwickshire M.C.

A meeting of the committee with the object of reviving this club was held on Tuesday evening last.

Manchester M.C.

A very busy year is anticipated for this club, comprising an Easter trial, hill-climbs, reliability trials, and gymkhanas. A meeting has been arranged for the 13th inst., at the Albion Hotel, Piccadilly, Manchester, to which all interested are invited. The hon. secretary is Mr. H. D. Ashworth, British Electron, Ltd., Hood St., Manchester.

Liverpool M.C.

A smoking concert will be held on March 19th, at St. Margaret's Hall, Parkway, Liverpool, which is free to all motorists. Tickets from the hon. secretary, Lt. N. Dean, 22, Ford Street, Liverpool.

The date of the opening run to Llangollen has been altered to April 13th. This run will embody an appearance competition, and lady members will act as judges.

There is no entrance fee to this club, and, for motor cyclists, the subscription is 21s. per annum, which includes the full benefits of the A.C.U.

M.C.C. for Kentish Town.

We are informed that it is intended to establish a motor cycle club in the Kentish Town district (N.W. London). Any motor cyclists in that part who are interested are invited to write to, or call on, Mr. W. C. Mison, 126, Kentish Town Road, London, N.W.5. As soon as sufficient applications have been received to warrant it, a meeting will be called for the purpose of electing the committee. The Club will be affiliated to the A.C.U.

A Motor Cycle Club for Blaenavon.

At a meeting of motor cyclists held in Blaenavon recently, it was decided to form a local motor cycle club. Those interested should communicate with the hon. secretary, Mr. B. R. Evans, 22, Glantorvaen Terrace, Blaenavon, Mon.

N.M.C.F.U.

Rapid strides are being made by the Leeds branch in an endeavour to become the premier section of the Union. Meetings have been held to discuss the fuel question, which have attracted a great deal of notice in the local press, and are likely to be of benefit in obtaining better and cheaper supplies of benzole. Sporting events, competitions, and club runs for the season are being arranged. The hon. secretary is Mr. T. W. Lancaster, of Evelyn Street, Chapeltown Road, Leeds. The next open meeting is on the 10th inst.

THE MOTOR CYCLISTS' PARLIAMENT.

An Appeal to all Riders for Combined Action. By Major S. R. Axford, O.B.E.

IT is curious, but various conversations I have held with motor cyclists show that there appears to be a hazy notion concerning the Auto-Cycle Union. Ask the average motor cyclist what the A.C.U. is and means, and he will probably reply: "Oh! the Auto-Cycle Union controls the sport and that sort of thing, you know!" anything more definite he is unable to mention.

Such is my excuse for dealing with the constitution, the activities, and the aims of the A.C.U., in this article.

It is not possible to treat the subject in more than a sketchy manner owing to the fact that an exhaustive treatise on this subject would fill many pages.

In the first place, it may be interesting to state that the A.C.U. is an offspring from the Royal Automobile Club. The R.A.C. was founded in 1897, as a society of encouragement for the motor and allied industries in the United Kingdom, and, being the supreme motoring authority in this country, represents the United Kingdom on the International Association of recognised automobile clubs.

The Aims and Objects.

In 1903, the R.A.C., with the concurrence of the National Cyclists' Union, formed the Auto-Cycle Club, now known as the Auto-Cycle Union, and this latter body represents the United Kingdom on the Federation Internationale des Clubs Motocyclistes.

The avowed objects of the Auto-Cycle Union are, and always have been: (a) to foster the pastime of motor cycling, and to act as a society of encouragement; (b) to safeguard the rights and privileges of members, and to take action, where advisable, in cases where general principles affecting the rights of motor cyclists are involved; (c) to provide a centre of information on motor cycling matters; (d) to make and administer rules and regulations for the government of motor cycle racing and other competitions.

Hitherto, I am afraid that the majority of motor cyclists, certainly the sporting element, have considered object (d) the Alpha and Omega of the A.C.U.'s duties. This is by no means so, for a careful perusal of object (a) will reveal a far greater aim, and one that in itself should clearly and insistently demand the material support of every motor cyclist. The obvious method of giving such support is to join the A.C.U., and from what I am privileged to know of the "plans of campaign," I can unhesitatingly assure those motor cyclists who are not yet members that to remain non-members is the greatest mistake possible—that is if they have the slightest interest in the development of the pastime, in its freedom from the tyranny of combines, or in obtaining redress from unfair legislation.

Membership is open, of course, to both ladies and gentlemen, and the benefits apply equally in England, Scotland, and Wales, and also Ireland except as regards the "Get you home" scheme.

Motor cyclists who are members of an affiliated club are in a very favourable position, as under Division B they get advantages which, as individual members,

they could not get for less than 10s. (Division B means that their club pays a capitation fee of 5s. per member.) Any member of an affiliated club may enjoy the full privileges of membership of the A.C.U., including the benefits of the "Get you home" scheme, etc., by an extra payment of 2s. 6d. This means that Division C, in which he would then be classified, offers to club members the full benefits, costing individual members 10s. at a cost of 7s. 6d., so there is obviously a great inducement for a member to join through a local affiliated club. This scheme should also appeal greatly to the clubs themselves, for it certainly is an incentive to the average motor cyclist to join his local club.

The officers of the A.C.U. consist of a president, vice-presidents, and a committee of forty-four members. The president and vice-presidents are, of course, *ex-officio* members of the committee.

Representations on the committee are as follows: Club members, 20; individual members, 12; and R.A.C. nominees, 12.

It will be seen therefore that the R.A.C. representatives have no actual controlling power, as they are in the minority, except, of course, their power as ordinary members of the committee.

There are seats for thirty-two absolute representatives of motor cyclists on the committee, and therefore if motor cyclists themselves will see that only the right men are elected the pastime should go ahead like steam.

Committee Nominations.

Before going further, it might be well to remind club secretaries of Rule 31, particularly with regard to the payment of capitation fees, for, unless they are paid as notified in Rule 15, clubs will find that they are not in a position to nominate members on the committee.

This rule disqualifying clubs from nominating members for the committee is perfectly fair, for it is a guarantee of good faith as to size of membership and consequent voting power.

Each club is entitled to one voting paper for each twenty-five members or portion thereof. Without the rule before-mentioned it would, of course, be possible for an optimistic club secretary to estimate his club membership at an absurdly high figure. Payment of capitation fees on his estimate is a steady influence.

It is proposed that in future the committee shall meet *en plein* every other month, and at different provincial centres as well as London. The railway fares of committeemen will be paid by the A.C.U. These meetings will be open to the press. I certainly think that the quorum should not be less than fifteen, as it is obvious that much work must be done by sub-committees, which should have executive powers within their terms of reference, and it would be unwise that the quorum of the General Committee should be too small in such circumstances for obvious reasons. It should also be ruled that at least two members of the Management Committee must be present at meetings of a sub-committee before their decisions can become executive ones.

To give a sub-committee executive powers would mean a great speeding up, and the interminable process of referring recommendations to the Management and General Committees, etc., with its waste of time, would be eliminated.

The Birmingham Meeting.

Before dealing with the annual general meeting to be held in Birmingham on March 22nd, I would like to make it quite clear that the management and financial control of the Union is vested *solely* in the committee, which means that, if a poor standard of nominees is elected, motor cyclists will surely rue it. On the other hand, if a sound energetic committee results, things will surely "move."

The old system whereby the annual general meeting had executive power was hopelessly wrong, for it obviously needed but a few "Bolshevists" to attend *en masse*, and by a snatch vote wreck the whole policy and constitution of the Union. It would be as reasonable to call a meeting of the electorate of the United Kingdom to reverse Acts of Parliament.

I can see a most interesting period ahead, a period moreover in which the fighting organisation only will obtain its end.

Therefore, the genial personality—if he has no other qualifications—is useless on the committee. Every motor cyclist has his chance at the annual general meeting of deciding who shall fight for him; therefore, in heaven's name, elect fighters! The man who sits at the committee table like a deaf mute (and who does not know this type) is not the man wanted. Bear in mind that I am not thinking of any particular individuals for whom I am either for or against. I only wish to emphasise the principle that negative personalities are far worse than useless—they fill the place of more fit men.

I am not, of course, suggesting that my remarks are not labouring the obvious, but I offer no apology for them, inasmuch as the lethargy of most humans is well known, but if I can spur even 50% of the motor cyclists of Great Britain to take a lively interest in their own welfare I shall consider my efforts approaching sublime heights of accomplishment.

As a last word, therefore, may I urge all motor cyclists—whether members or not—who can possibly attend the annual general meeting to do so.

Clubs must forward the names of nominees to reach the A.C.U. offices by March 15th.

Annual general meeting at the Digbeth Institute at Birmingham March 22nd.

Individual members' annual meeting at Birmingham March 22nd.

Results of election to be published by the A.C.U. before April 5th.

First meeting of new committee to be held on April 17th.

It is also intended that after the annual general meeting at Birmingham on the 22nd the meeting should be thrown open to the whole motor cycling public, when many world-renowned motor cyclists will speak. Motor cyclists should determine, by hook or by crook, to attend this victory meeting.

THE METRO-TYLER LIGHTWEIGHTS.

Two Examples of a 295 c.c. Two-stroke.

The touring model Metro-Tyler two-stroke. The sporting model, fitted with disc wheels and dropped handle-bars.

WE announced some time ago that the Tyler Apparatus Co., Ltd., Banister Road, N. Kensington, and the Metro Two-stroke Co., had joined forces. The first results of the amalgamation are the two new lightweights illustrated here. One of these is a single-gear, sporting model, with disc wheels which give it a very distinctive appearance, and the other a more conventional machine with two-speed gear.

The bore and stroke of the Metro engine are 70 mm. and 77 mm. respec-

tively, which give a capacity of 296 c.c. It is of the usual three-port type, with a three-ring piston. Die-cast white metal bearings are used for the crankshaft and "big-end." These bearings are inexpensive and, owing to their simple design, easy to renew.

Lubrication is carried out by means of a Best and Lloyd sight-feed pump on the tank which supplies oil direct to the induction pipe, whence it is carried by suction to the cylinder walls, the crankshaft bearings being fed from the base

of the cylinder through vertical oil ducts drilled on the side of the crank case.

The mudguarding, both at the front and rear wheels, is well carried out, while the specification of both models includes Brampton Biflex forks, Lycett's pan saddle, 26 x 2½ Clincher tyres. Both machines are enamelled dark red, which is relieved by black lines. Prices range from £46 for the single-speed model without wheel discs to £54 10s., the price of the sports model with disc wheels and two-speed gear.

THE 1919 RADCO.

An Efficient Two-stroke Lightweight.

ONE of the best known of the lower-priced lightweights before the war was the 2½ h.p. Radco, which, despite its exceedingly low price, was quite an efficient little machine. For example, we recall that it was entered in several competitions, and almost invariably obtained an award. This consistent good running of the engine may have been responsible for the honour it received by being copied so closely by a well-known American concern.

The 1919 model is very little altered, except that Druid forks are now fitted in place of the more simple Radco type embodied in the earlier models, while the weight is approximately 100 lb. 26 x 2in. wheels with beaded edge Clincher de Luxe tyres are standard.

With the exception of the magneto, the engine and its equipment remain as before. The bore and stroke are 62 mm. and 70 mm., the capacity being 211 c.c. The lubrication is by sight drip feed, the

oil being carried to the induction pipe. The single-speed and two-speed models are offered at 36 and 43 guineas respectively.

The makers are Messrs. E. A. Radnall and Co., Vauxhall Works, Dartmouth Street, Birmingham.

The Radco two-stroke model, fitted with two-speed countershaft gear.

ROAD REPORTS.

WE have received the following information as to the condition of certain roads:

The road from Uxbridge to Ealing is reported by a reader to be the worst he has yet traversed, and is one long stretch of pot-holes of varying size for the whole distance.

Alcester-Wellington, *via* Bromsgrove, Kidderminster, and Bridgnorth.—Very fair.

Stratford-Alcester.—Bad.

Wellington-Whitchurch.—Good, last few miles in perfect condition.

Whitchurch-Warrington, *via* Tarporley.—Good.

Windsor-Oxford, *via* Henley and Benson.—Good, especially near Henley.

Oxford-Stratford-on-Avon.—Fair, but a few miles are bad.

The Lake District, Newby Bridge to Windermere.—Fair, broken in places.

Windermere to Ambleside.—Fair, rather bumpy.

Ambleside to Grasmere.—Fair, very greasy in wet weather.

Grasmere to Keswick.—Good all the way.

Keswick to Penrith, *via* Greystones.—Very good.

Kendal to Bowness, *via* Crook.—Excellent.

Penrith to Shap village.—Very good, except for one or two short stretches.

Shap to Shap summit.—Excellent.

Shap summit to Kendal.—Very bad indeed.

A reader requires information concerning the road from Inverness to Wick.

Another reader requires information as to the state of the roads in North Somersetshire generally.

SOME SNAGS FOR CLUB SECRETARIES.

Problems connected with the Preparation of a Sporting Programme.

FOREWORD. Now that the clubs are coming to life so rapidly and vigorously, the time has come when the club officials must take stock of present conditions and rule their actions accordingly, and the policy of the principal events will have to be studied from an entirely different viewpoint from that of 1914. The following article shows how at least one wideawake club secretary has tackled the problem.

ANY couple of motor cyclists foregather so chummily at a chance meeting on the road that the running of a successful club looks the easiest job in the world. In actual practice, no secretary occupies a bed of roses, and a few warnings from an old hand may be of service to provincial clubs just starting or restarting.

In the first place, a large membership is essential and is difficult to obtain in small towns. Numbers are requisite for several reasons. In the first place, the annual budget will be quite imposing, and plenty of subscriptions alone can preserve the club from bankruptcy: niggardliness in running competitions and social events is a great damper. In the second place, motor cyclists are drawn from all strata of society and do not necessarily mix well. Their womenfolk are often like oil and water, and in these days of sidecars and cycle cars you must make the club attractive to the fair sex. If the average attendance at a club fixture consists of ten men who do not know each other, except by sight, and six women who do not want to know each other, the club will be a wash-out. An average attendance of sixteen implies a paper membership of 100 in many localities. On the other hand if you can count on an average attendance of thirty, the various little cliques—even of petticoats—can dissolve into their own eddies when required. But an average attendance of thirty implies either a paper membership of 200 or a very keen membership of 100, shepherded and coaxed by a super-efficient secretary.

Two Problems.

Having founded your club and secured your membership, you are beset by two practical problems:

- (a) To satisfy your keen members.
- (b) To make your slack members keen.

It is a toss-up which problem is the more difficult. Amongst your keen members you have riders who want a competition every week (some of them want it on early closing day, others on Saturday): riders who want social runs to a tea house thirty miles away at 20 m.p.h., and riders who want "scraps" at 35 m.p.h. to a public house eighty miles away; members of each of these two sets are variously at leisure on Thursday and on Saturday. When you have a competition, 75% of the riders quarrel about the management, timekeeping, conditions, and prizes: when there is no competition, half the men blaze away to the tea destination and the rest complain of their unsociability. The next week you put the captain in the van and forbid anybody to pass him, whereupon the hot heads whisper about a Sunday school treat. You require the tact of an archangel, the patience of Job, the ruthlessness of Hindenburg, and a dash of George Robey to weld the outfit into a contented family. But, generally speaking, you will gradually build up a satisfactory club if you can avoid serious trouble over the competitions.

A Fifty-guinea Cup.

There are two main snags in this connection. The local M.P. will probably give you a fifty-guinea cup, which will be the *pièce de résistance* amongst a catalogue of small fry, ranging from copper kettles to sparking plugs. That fifty-guinea cup may lead the secretary of the A.C.U. to mark your town on his map as "unclubbable." Only one man can win it per season, but, when he has won it, all the rest will contend that they ought to have won it. The organisation of the big event must be cast iron, waterproof, swindle-tight. Get Ebbelwhite to time it, S. F. Edge to judge it, and a large posse of Scotland Yard men to O.K. the non-stops. Otherwise you will privately bribe the local Bill Sikes to pinch that cup during the next winter.

Secondly, it is well to avoid reliance on inexperienced local helpers in competitions, unless you are a shrewd judge of men. In the consumption trial, for instance, Elijah Simkins puts up a record of 432 m.p.g., and you discover that he is going to marry the sister of your volunteer marshal, who was responsible for measuring exactly a quart into every rider's tank. Also take a strong line about such things as weather. You have no hill suitable for the climbing championship within forty miles. You select a hill forty miles away, and on the appointed day it rains cats and dogs. Out of twenty-three entrants eight turn up. Shall you run the climb off or not? If you did not make it clear beforehand that the event will be held wet or fine, the committee will probably declare it null and void, and the riders who braved the elements and scooped the pool will resign.

The Social Side.

The social side of club life is even more exhausting, because motor cycling is essentially unsociable. There is no real pleasure in touring in crowds, and conversation is not too easy *à deux* on a sidecar: many a happy home has been wrecked because Angelina asked Edwin to repeat a remark made from a superior altitude of 3ft. with a pipe in his mouth and a coat collar turned up to his ears. My own view of these difficult matters is that a club run should consist of a rendezvous, where members may inspect machines; a go-as-you-please tour to a common destination—let the speed-irons try to average forty, and the potterers burble along at fifteen; and tea together, preferably at a show place, where the riders may swap yarns, make acquaintances, try their machines up a hill, and visit an old castle or inspect Mr. Profiteer's prize shorthorns.

The conversion of slack members into active members is a thorny task, but must be faced. Make them feel that the club fixtures are worth attending and what they miss by absence: make them see the members missed them, and hope they are coming next week. When at last they do turn out, treat them as if they were your personal guests, and as if you were responsible for their entertainment.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

WOODEN MODELS.

Sir,—May I point out that there is a slight error in your report of the paper on motor cycles, which I gave before the I.A.E. recently. The very excellent wooden models of frames were not used to illustrate the paper, but were produced and exhibited by Mr. M. Peters in the subsequent discussion.

I shall be glad if you will kindly insert this correction, as I consider that Mr. Peters is deserving of considerable credit for the introduction of a really useful method of examining frame design.

D. S. HEATHER, B.Sc., A.M.I.A.E.

REPORTING THE T.T. FROM THE AIR.

Sir,—May I use a little of your valuable space to give "Road Rider" my opinions on "Reporting the T.T. from the air."

Certainly his suggestion of conveying the reports and photographs from Douglas to Coventry by air is quite brilliant, but I should like to see anyone developing plates in a DH9, especially if it were "bumpy"! I should also like to see literary representatives with their aluminium typewriters carefully making out their reports amidst the din of four 400 h.p. Liberty engines, or even one in the case of the DH9!

If he intends to take photographs of the race from the air, I can assure him his efforts would not meet with much approval. Just an ordinary aerial photograph with a few little dots along the road would represent the complete Isle of Man T.T., all of which could be got on one plate. Of course, I may have taken the wrong idea about the photographs. "Road Rider" may not mean aerial ones.

He says, "poor visibility" is a sad nuisance in long-distance daylight flying. In five years improved instruments should render the aerial navigator master of almost all conceivable weather conditions." However improved the instruments will be, they cannot improve the weather itself, and so render the aerial navigator a "master."

In conclusion, I for one would not like to have 'planes zooming overhead during a race!

R.A.F. OBSERVER.

Southport.

ALUMINIUM COOLING.

Sir,—Permit me to thank your correspondent, Mr. E. Russell (page 167), for a half-hour's amusement. I venture to think that this emotion will be shared by many of your readers, when it is pointed out that his letter inevitably implies that neither Mr. Lanchester nor myself had heard of coefficients of expansion, or that we had entirely failed to take into consideration the effect of such factors!

"Any method," says Mr. Russell, "of casting or shrinking the ribs over a barrel is bad." He then proceeds to explain that his method is to cast the one on to the other! How this abolishes the (alleged serious) difference between the coefficients of expansion is not explained.

Would it not appear that, supposing differential expansion to have the serious effects he alleges, the metal at the roots of his ins must necessarily be in an extreme state of tension—a condition aggravated by every additional degree of working temperature, and tending, especially under vibration, to distortion and rupture?

To revert to those alleged defects in the most successful and extensively-applied system yet evolved, it would be interesting to know upon what basis Mr. Russell's very sweeping statements are made. I may have to bow to Mr. R.'s technical authority, but regret to say that his name is previously unknown to me. Will he therefore be good

enough to inform us how many instances he has personally verified of the aluminium parting from the iron liner; the types of engines, system of fitting, degree of separation, percentage of the "great loss of cooling effect" (*sic*), etc.?

That a cylinder made as illustrated would have a neat appearance is apparent. That it would prove superior to an all-iron cylinder, under equal conditions, is most probable. That it may prove a serious addition to two-stroke improvement is, in my opinion, quite improbable; no attempt being made to utilise two of the most valuable properties of the metal, and a basic principle, vital to success on any considerable scale, being totally ignored.

I may be permitted to remark that I have never seen or heard of a case of looseness or of impaired heat-transmission as described by Mr. Russell. Further, upon the data and experience of nearly a quarter of a century, I have grounds for suspecting that this defect in my technical education may never be removed, so far as my own work is concerned, even should I continue to use those "bad" methods which are really so superior, practically and theoretically, to the illusive "improvement" illustrated on page 167. The latter design is quite all right for what it is and so far as it goes, but its efficiency will not be improved by the belated discovery of the nests of mares that foaled over a score of years ago.

R. AYTON.

HOME-MADE VAPORISER.

Sir,—I am forwarding you a photograph of my 8 h.p. Grandex-Jap, with a vaporiser of my own make over the rear exhaust valve, which I think will be useful to some of your readers. I have given it a good testing on a previous mount of mine, a 3 h.p. twin Enfield with light sidecar,

A valve cap vaporiser used by Mr. G. Frid.

on which I used paraffin only, all through the bad weather of 1916 and 1917, and I got splendid results. I am also getting a big saving on the Jap. On a run from Ponders End to Sudbury, in Suffolk, and back, with my wife and three children, the youngest being five years old, I did the 139 miles on three gallons and one pint of war spirit.

I hope this will be of interest and useful to others.

G. FRID.

DETACHABLE CYLINDER HEADS.

Sir,—We were very much interested in "Ixion's" comments *re* the above, in your issue of the 13th ult. It is true that many manufacturers are coquetting with the detachable cylinder head: indeed, we notice that two of the leading manufacturers have definitely decided to adopt the detachable cylinder head on their new models. On the Blackburne engine we have fitted detachable cylinder heads for a great many years, and, unlike other manufacturers, we have never abandoned them in favour of the solid cylinder.

The question of the design of a suitable head, however, is not entirely simple, and a great deal of time and thought was spent before we arrived at the design now adopted as standard on all Blackburne engines. This point we would strongly emphasize, as many people seem to be under the impression that it is merely a case of putting a "lid" on a cylinder, so to speak, whereas there are many snags and pitfalls to be avoided. The stresses set up in a casting of this peculiar shape have to be carefully studied, and we claim that our present design of cylinder head is one of the outstanding features of the Blackburne engine.

With regard to "Ixion's" remark that "amateur owners experienced difficulty in remaking the joint," may we say that our correspondence files do not indicate that owners of Blackburne machines have had trouble in this direction.

BURNEY AND BLACKBURNE, LTD.

G. Leivers, A.M.I.Mech.E., Director.

COMMUNAL GARAGES.

Sir,—Being greatly interested in the article by "F.A.S." entitled "The Motor Cycle, where to keep it," published in your issue of January 2nd, 1919, I have been keenly disappointed at the very meagre attention which seems to have been given the subject raised, viz., "Communal Garages." I reside in an industrial centre (notorious for its smoke and the steels which have made so important an advance in metallurgy) and the houses follow the same law as appertains to other industrial districts—the crowding of as many houses as possible on each acre of land. These

Plan of a communal garage suggested by Mr. W. Wright.

houses are built in rows and have no convenience for storing any mechanical contrivance, not even a push cycle, when not in use. The possibilities of communal garages appealed to me very much, and being connected with a union having a local membership of 800 I lost no time in bringing the subject forward, with the result that we placed it on our immediate programme, and anticipate having at least one communal garage in each district, where each member can have his own cubicle, a covered-in shed for common use to clean and make other necessary adjustments from time to time, and a stores where motor fuel, oil, and other accessories can be obtained as required; also, a well-equipped workshop, where any small replacement can be made, will be added where circumstances permit. This is rather an ambitious programme, but with the organisation we have already in Sheffield it should be fairly easy of accomplishment. We already distribute benzole on these lines, having one or more stewards in each district, who receive the benzole and distribute it locally. These stewards would have charge of the stores and workshop. It would scarcely be necessary to stock more than, say, 100 galls. of benzole, 10 galls. of oil,

and one tyre each of the sizes mostly asked for, as it is only a question of a few days to obtain renewals and other accessories. Those of our members who do not need a cubicle would have the benefit of communal trading in motor fuel, oil, and other accessories, the use of the workshop, and cleaning appliances, etc.; last but not least the advice and help of the experts who are always found in every group of motor cyclists. This matter has been fully discussed and will be commenced as soon as we settle the details of expenditure, etc. In outline I imagine the plan of the communal garages as in the accompanying sketch.

W. WRIGHT.

RUSTLESS STEEL.

Sir,—Your correspondent E. W. Walford appears to be misinformed about the mechanical properties of this steel.

He quotes it as having an ultimate tensile strength of about forty tons. Like all alloy steels its mechanical properties can be widely varied by heat treatment. Rustless steel can quite readily be given an ultimate tensile strength of 100 tons by water or oil hardening from 900°C.

Mr. Walford is also mistaken when he says that this steel is nearly as good as tungsten steel in regard to pitting and absence of deformation when used for exhaust valves. It is considerably better. I have seen two exhaust valves, one made from rustless steel and one made from the tungsten steel previously used, which had both been run in the same engine (Rolls Royce) for an equal length of time. The tungsten steel valve was badly pitted on the stem and cracked on the seating and also scaled, whereas the rustless steel valve was not appreciably affected. This observation relating to the two valves is, I believe, merely an instance of experience which was quite general during the last year or two of the war.

The only respect in which tungsten steel has proved superior to rustless steel is its greater strength at very high temperatures. By suitable modifications in composition, for this purpose rustless steel has been made quite as strong as tungsten steel at high temperatures.

LEO. T. BREARLEY,

The Firth-Brearley Stainless Steel Syndicate, Ltd.

THE ADVANTAGES OF A TWO-STROKE.

Sir,—Apparently "Enquirer" has taken F. W. Varney's ecstatic effusion *re* his Levis as an accurate guide by which to measure his own requirements.

Average speeds of thirty-five with sidecar and forty-five solo are possible with a 2½ h.p. Levis under one condition only—downhill. I suggest to "F.W.V." that a new speedometer might register his m.p.h. with more certainty.

"Enquirer" will with experience discover that for efficient and care-free dual purposes a cubic capacity of approximately 600 is necessary. A 500 c.c. will admittedly give excellent service; but, you old hands, what of that long, stiff gradient, heavy surface, head wind and rain, and a konk out halfway with two fair passengers? And—ugh!—requesting them to place their dear little feet in the mud and walk to the top. The American designer who doles out 1,000 c.c. knows something of meagre capacity engines.

A. STANLEY BLICK.

WHAT SHALL WE WEAR?

Sir,—I am afraid that the article by Miss Gardener is calculated to discourage women motor cyclists more than anything I have ever read. As clothed in her excessive bundle of oddments, she seems to have suffered everything, from chilled fingers to water trickling down her back and on to her legs from her lap.

Now, I have ridden a Douglas and a small Enfield during the last two winters, and have not experienced any of these things. I wear an ordinary man's short, double-breasted Burberry and high boots, lined gauntlet gloves, and ordinary velour hat, with a ribbon under the chin. The rest of my clothes I do not change for motor cycling. I always wear short skirts. For my journeys (including one on February 5th, in the snow) I can dress myself in five minutes easily. In warm weather I wear shoes, stockings, and ordinary clothes.

In the summer it is exhilarating and glorious to feel the air going right through all one's clothes. I consider it is the greatest mistake to dress up excessively for motor cycling. Use as little modification to one's ordinary clothes as possible, is my advice, and find out by experience in each individual case what you feel you want.

(Miss) PHYLLIS VERNON.

MOTOR CYCLES FOR THE MAIMED.

Sir,—I should be glad to know from any other reader of *The Motor Cycle*, who has a disabled, stiffened, or amputated right leg, what make or makes (and their horse-power) have no right-foot controls.

I am anxious to get a second-hand 2½-3½ h.p. two-stroke, but if none is quite suitable I should like a 3½ to 6 h.p. four-stroke.

I am a reader of your journal, and I may tell you that it gives me three or four evenings' delightful reading every week.

DEVEREUSE H. WHYTE.

MAKERS AND PROMPT SERVICE.

Sir,—In your issue of Feb. 13th I noticed that "G.R." was worried by the fact that he wanted to cancel his order for a machine, and the firm he ordered it from refused to cancel it. I should like first to state my experience in that direction.

Two months ago I ordered a Big 4 Norton sidecar from Messrs. Godfreys, Ltd., to be delivered this February. Only thirty days ago I discovered that I should have to cancel the order as I have to go out East. I wrote Messrs. Godfreys and asked if they would cancel the order, and explained why. By return of post I received a very courteous letter and also a cheque for £5, the deposit I paid in December. This difference in treatment, I think, well illustrates the difference in firms. I do not know from which firm "G.R." ordered his machine, but I think I know where he will go for another machine when he wants one. I was treated exceptionally well by Messrs. Godfreys, and I have no interest in the firm whatever, except that of a prospective customer. When possible I shall go straight to them for my machine.

W. T. VIZER-HARMER (LIEUT.).

Sir,—I should like to endorse the letter of "Lieut." in your issue for February 6th. I have dealt with the Hendee Co. for nearly two years, and nothing can exceed the promptness and politeness of their business methods. I have never ordered a spare part without receiving it by return of post. Just before Christmas I wished to fit disc wheels to my machine, and wrote on Monday, December 23rd, asking them, if possible, to send them at once. They were in my house with all necessary screws, nuts, etc., on Thursday evening. I think such treatment deserves recognition by those who enjoy it.

L. ENSELL.

Sir,—I should like to bring before your notice the way in which Messrs. H. Collier and Sons, Ltd., 44, Plumstead Road, Plumstead, London, S.E., have treated me. I purchased from them some months back a pair of ball races and had no occasion to use them, having sold the motor cycle. I wrote them returning the ball races and asking them to allow me what they thought best. I was agreeably surprised to find they refunded me the full amount, namely, 19/6. I think this is a most businesslike and satisfactory way to treat customers, and hope other readers of your paper have had the same experience.

This firm never hangs up orders for spares if no remittance is sent to cover, but helps one by despatching immediately. Perhaps you will be able to mention this in your paper.

J. H. GARDINER.

THE GRADUAL PAYMENT SYSTEM.

Sir,—I have recently been in communication with two of the leading motor cycle dealers, namely, Rider Troward and Godfrey, and both have informed me of the discontinuance of their gradual payment systems, both stating that this is due to the shortage of second-hand machines.

This action will rob many ex-soldiers of the joys of the open road this forthcoming summer at least. Returning from Army life with only a few pounds in their pockets, many must be left to gaze enviously at the munition worker with his £140 combination, whereas the continuance of the gradual payment system would have given them opportunity to get hold of a modest 'bus and enjoy the delights of motor cycling.

During the past two years, whilst the restraining hand of "Dora" has been upon us, dealers have been only too glad to sell on any terms, and many munition workers and such have been paying towards the purchase of a mount, but we unfortunate souls who were in khaki had no opportunity of this, and now, when at last we are able again to take up the threads of a peaceful existence, up go the prices, and the schemes that would have enabled us to materialise our long-

looked-forward-to dreams have vanished, and we are left kicking about "busless" whilst our more fortunate brethren are speeding away on the roads and over the country for which we did our humble best.

Is there a grateful and reliable dealer who will accept an order for a decent second-hand combination on the usual easy payment terms?

Wishing you every success, and thanking you for keeping us posted in motor matters whilst we squared up things over there,

F.E.H.B.

Manchester.

REPAIRING BROKEN CYLINDERS.

Sir,—Referring to the article which appeared in your issue of Feb. 13th, describing some repairs and improvements carried out on a Premier motor cycle, your contributor appears to be labouring under some misapprehension. He states, in regard to the broken cylinders which he so skilfully managed to repair, that "welding was out of the question, the broken portions of the combustion head being missing." We replace combustion heads in such conditions, however bad, and, although the work obviously calls for more than the ordinary amount of skill, there is no difficulty about it. We often have cases of four-cylinder engines in which three out of the four combustion heads have been entirely broken away, whilst instances in which two heads are gone are almost commonplace.

We fully appreciate the resource and ingenuity exhibited in carrying out the work described in the article, and we are sure your contributor will not mind our putting him right upon this point. We think, indeed, the information may be both of value and interest, not only to him, but to your readers in general. We may add that we have in hand at this present moment several cases of damaged motor cycle engines, the breakages in many instances being of precisely the same character as those in which your contributor thinks that welding is out of the question.

THE NEW WELDING CO.

NOISY MOTOR CYCLES.

Sir,—In your issue of February 6th you give an extract from *The Times* that the motor cycle is abominably and unnecessarily noisy. At any rate, the first adjective expresses public opinion. Although I am an engineer and take a great interest in motor cycles, I cannot deny that *The Times* statement is correct. I have passed many hundreds of motor cycles on the roads at different times, and there is only one single-cylinder machine (Sunbeam) that in my opinion does not make an undue noise. Occasionally a P. and M. is in this category for quietness. There is another make with a single-cylinder that makes a hideous row, and I asked at the local agency why the machines always make such a noise, and the man agreed that the machines in question did make a perfect racket. I would prohibit such machines from using the road.

Manufacturers must remember that it is not in their interest to cater only for youths and so-called speed merchants, who often consider that noise is speed. Public opinion is worth considering when it can be cultivated by efficient silencers and intelligent design. Of course, every manufacturer will think his machine quiet, but the fact remains that motor cycles are, in the main, abominably and unnecessarily noisy, and a general nuisance in this respect.

Manchester

G.F.S.

[Other machines than those mentioned are entirely satisfactory in respect of silence.—ED.]

BOOKS FOR MOTOR CYCLISTS**MOTOR CYCLES AND HOW TO MANAGE THEM.**

The recognised standard text book of the motor cycle: deals with all types of machines and with every part of the machine. 400 illustrations.

Price 2/6 net. By post, 2/10.

HINTS AND TIPS FOR MOTOR CYCLISTS.

A valuable collection of useful "wrinkles" and items of information concerning the running, management, and repair of motor cycles.

Price 2/- net. By post, 2/3.

TRACING TROUBLES.

Motor Cycle Faults, Their Identification, and Their Remedies Fully Explained.

Price 2/- net. By post, 2/2.

Obtainable by post (remittance with order) from

ILIFFE & SONS Ltd., 20, Tudor Street, London, E.C.4
or of leading Booksellers and Railway Bookstalls.

QUESTIONS AND REPLIES

Magneto Brushes.

Does a Bosch magneto require attention as regards carbon brushes? I have been advised to take mine apart and put in new brushes, although the machine has never given any trouble, and I think it best to leave well alone.—E.D.

The brush on the collector ring, to which the high-tension wire is connected, is liable to wear or break. It may be examined without difficulty by screwing the vulcanite terminal out. If there is plenty of carbon left, it does not require renewing. The end of the brush should be either flat or slightly concave in section, and may be trimmed up with fine sandpaper.

A Legal Query.

Wishing to purchase a motor cycle, I answered the following advertisement: "Motor cycle. 2 h.p., B. and B., U.H. magneto, as new." Eventually I bought it. It will rev. on the stand, sometimes, but, although I have spent a lot of money on it, it will not go. How do I stand with regard to a prosecution for "misrepresentation"? One of the pedals fell off the other day.—C.G.

You do not say how long it is since you purchased the machine, but you do state that you have spent a lot of money on it, which goes to show that you have had it some time. As soon as you found that the machine was not as represented, you should have returned it

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

to the seller and demanded your money back. Your proper remedy is to commence an action for damages for misrepresentation, and you should put this in the hands of a solicitor, so that he could advise you as to whether you have sufficient evidence. With regard to the question of fraudulent misrepresentation, your letter does not sufficiently indicate that the seller was guilty of criminal fraud, but, if you wished, you could discuss this with your chief constable. However, from the point of view of your own pocket, it would be best to drop the question of any criminal prosecution and proceed for damages on your solicitor's advice, that is, if the party you purchased the motor cycle from is worth suing.

The 1919 5-6 h.p. spring frame A.J.S., a full description of which was given last week. Many new features are incorporated in the new model, detachable cylinder heads being adopted once more. Among other components of the engine that have received detail alteration are the cam wheels and their shafts, exhaust valve lifter mechanism, exhaust pipe angle, and the valve springs.

Overflowing Petrol.

The petrol drips out of the air ports of my carburettor spray chamber.

At the bottom of the latter there is a cone-shaped arrangement, with holes in, through which the petrol drips the very second I stop. Whether it is like this going along, I cannot say for certain, but I think it is, because of the petrol consumed.—R.I.P.

The petrol level is evidently too high. The float may have petrol inside it, which will have to be removed by putting the float in boiling water until the spirit is evaporated. The hole must then be closed with solder. If the float is all right the needle should be ground in and the level lowered by tapping the needle collar slightly toward the top of the needle.

Operation of a Hub Gear.

I have a Humber motor bicycle fitted with a two-speed hub. Would you tell me how I get the second speed, as there are three pedals? That on the right is the band brake, and the one on the left is the pedal which gives the free engine position. Is the inside one on the left the second speed, or only another band brake?—T.W.C.

The low speed pedal is the one without any catch; that is to say, the low speed is only in engagement while your foot is on the pedal; it operates the gear through a band. The top speed pedal has a catch which engages the top gear, keeping it permanently in until released. The other pedal, of course, is the ordinary rear brake.

Fitting a Variable Gear.

I have a 3½ h.p. 1912 Humber motor cycle and sidecar, fitted with a Roc two-speed hub gear. I find, however, that the second gear is not low enough to take the outfit, when loaded, up some of the hills I encounter, whereas I feel confident, if I had a lower gear to fall back upon, it would climb them well enough. Now, if I fitted a variable pulley, such as the Philipson, and, when I was on the second gear, started to use the variable pulley, would this be equivalent to a third or still lower gear? I am told by a friend that this would make no difference, as I should be still running on the second gear.—A.J.S.

Certainly, the fitting of a variable pulley would help matters greatly. Your friend is clearly in error. The fitting of a Philipson pulley would mean that you would get a variation in the gear ratio on both top and bottom speeds.

Liability for Repairs.

?

I bought a motor cycle from a friend, and went up to his place to try it with him, and it would not go. He suggested that we should take it to a garage, which we did. The bicycle is now ready, and the garage people want £2. Now who should pay the £2—the person from whom I bought the machine, or myself? There was nothing said at the time, but it was understood I bought the machine in running order.—J.C.M.

The question of liability depends on the ownership of the machine at the time it was repaired. If the sale had been completed, you would be responsible unless the machine was sold you as being in running order. As there was apparently an "understanding" to this effect (which would have to be proved), we think your friend should settle the matter, or, if he refuses, at least he should pay half.

Charging Accumulators.

?

In our town the electricity supply is alternating, fifty periods one hundred volts, and from this current I have adapted a device to charge the accumulator of my motor cycle consisting of two cells of two and a half volts each, with a total capacity of about sixteen ampère hours. The current being alternating, I am obliged to transform it to a direct current. This is done with the "Electrolytic Clapet," composed of a phosphate of soda bath, in which are immersed an aluminium plate and a lead plate, the first being joined to the positive of the accumulator, the second being joined to a lamp acting as resistance. (1.) Is a lamp of fifty watts suitable, or must I use twenty-five or one hundred watts? (2.) Is this device sound to charge accumulators? Is not the high voltage of the alternating current (100 volts) prejudicial to a good charge of a small accumulator? Or does the lamp used as resistance reduce the voltage sufficiently to ensure a good charge?—R.C. (Havre).

The Electrolytic rectifier you mention, known in this country as the "Noden Valve," is quite sound, and forms the best means of charging small accumulators from alternating current mains without the need of buying more expensive apparatus. (1.) A few precautions only are required to ensure successful working. The connections you give are correct. For an accumulator of sixteen ampère hours capacity either a fifty watt or one hundred watt lamp may be used as the resistance. If there is plenty of time for charging use the smaller lamp, as the lower rate will be better for the accumulator. The voltage of this lamp is important. The Noden valve itself will absorb about twenty volts, so that the lamp must be suitable for about eighty volts. If a lamp for one hundred volts is used hardly any current will pass. (2.) The valve is liable to become rather hot in working, and this must be watched. The solution should not come up higher than 2in. from the top of the containing jar. The aluminium should be pure, and the water should be distilled. The voltage is reduced to a suitable figure by the lamp mentioned above, and no harm will be done to the accumulator.

Taking a Motor Cycle to Australia.

?

Would you please tell me the cost of duty on a second-hand motor cycle brought into New South Wales (Australia), the owner travelling by the same boat? Its value is about £35. Also the cost of freight from England to Australia?—R.H.W.D.

The duty on a motor cycle taken into Australia is £10 per machine, while the rate of freight to Melbourne, Sydney, or Adelaide, is 20s. plus ten per cent. per ton.

Timing.

?

(1.) Would you be so good as to let me know the timing of a 4 h.p. single-cylinder J.A.P. engine? (2.) I have just overhauled my engine and cleaned it, and now find that there is no compression. Will this return when the engine has been running for a bit?—F.W.R.

(1.) Time the engine in the following manner: *Valves:* Set the exhaust valve to close just after the completion of the exhaust stroke. It will then commence to open when the piston is about one-seventh of the length of the stroke from the bottom of the firing stroke. The inlet should commence to open as the exhaust closes, and remain open for one complete stroke of the piston, or while

IMPORTANT NOTICE.**GOODS MADE IN GERMANY.**

The proprietors of this Journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication.

ILIFFE & SONS LTD.

the flywheels turn through 180°. *Magneto:* Remove the compression tap. Rotate the engine slowly until the piston is within three-eighths of an inch of the top of the compression stroke. (This point can be found by inserting a pencil or piece of wire through the compression tap opening.) This is the position the piston should be in when the igniting spark passes, which in turn takes place when the contact breaker points on the magneto just separate; it remains, therefore, to arrange that both these operations synchronise. Loosen the magneto sprocket, which is usually on a taper spindle. Rotate the magneto armature in its proper direction until the contact points just separate; take note that the piston is still in its proper position. Now fix the sprocket tightly, taking care not to move the armature in doing so, and again verify the position. In the case of magnetos which give a variable point for ignition, the lever should be set in the "Fully advanced" position prior to timing, i.e., as far as it will go in an opposite direction to the armature rotation. (2.) There should certainly be some compression after overhauling. If there is any at all, it is likely to improve after the engine has been run a little, but it

looks very much as if the valves were not seating properly, and the most likely cause of the trouble is that you have ground in the valves, which has had the effect of bringing the valve stems down lower, so that, unless the tappets are adjusted to make up for the difference, they do not seat properly.

READER'S REPLY.**A Mysterious Trouble.**

With reference to "H.F.K.'s" trouble, I have a 4 h.p. three-speed combination, which I recently dismantled for cleaning. When cleaned and reassembled the engine started first kick, so I thought there was not much wrong with it. I went for a trial trip with a passenger in the sidecar, and had gone about two miles when the engine started to knock. I retarded the spark and manipulated the air lever with no effect. The machine came to a standstill, apparently overheated. I looked round, but could not find anything wrong, and when it had cooled down it started off well again, only to repeat the trouble. When I got home I examined the engine to see if the timing was correct, and finding this was so examined the valves to see if they were sticking. These being quite all right, I took off the cylinder, but could not see anything wrong with the piston or rings. I then worked the valves up and down, and they seemed quite all right, but as they were covered with excess of oil I thought I would take them out and clean them. I got some paraffin, added a little petrol, and was cleaning with a brush when the exhaust valve guide dropped right off, hence the trouble. When the valve was in place the tension of the spring held the broken guide up against the cylinder, therefore it was impossible to detect the breakage.—A CONSTANT READER.

EXPERIENCES WANTED.

"A.H.J." (Chester)—Binks carburetter on a 5-6 h.p. Indian for solo and sidecar.

The Words of Godfrey's

THE AGENTS OF LON,

Concerning Deposits

(Another Chapter not to be found in the book of Artemas.)

NOW of all the laws of the land of En, none was more profitable to those agents whose ways were devious than the law of the essence of contract.

For it could be so wangled that the agent got the essence and the buyer the burden of the contract.

And the manner of the wangle was this: they would entice the public with smooth words, saying, "Lo, we can deliver to thee the machine thy soul desireth." And for some would they fix a date, and for others promise early deliveries.

And they did take deposits with orders.

Now, seeing the men who rode on wheels were sports and knew not the law, they did pay gladly, without stipulation.

Then, peradventure, the time would come that one of the men who had wasted his substance, or was tired of waiting for that which was always promised but never arrived, would seek to cancel his order.

Now, the righteous agent would straightway return the deposit—saying, "Friend, here is thy money which thou entrusteth to my care."

But, if otherwise, the agent would verily wangle the deposit to his own profit.

Take heed, and hearken unto the voice of Godfrey's, for it is in the reputation of a house that lyeth thy safety.

IN placing orders with GODFREY'S (or, in fact, with any Agent of repute), the Customer need have no fear concerning Deposits. GODFREY'S invariable rule is to return them in full should delivery not be required. But in view of the very illuminating answer to a "Legal Query—Essence of Contract," in a recent issue of "The Motor Cycle," it behoves the customer to select his agent with some discrimination.

Write for Godfrey's Full List of New Machines for which they can accept orders.

STILL THE BEST SELECTION

BELOW we give a selection from to-day's stock, which we think you will rightly say is the best in London. We think also that the prices will compare favourably with those asked elsewhere. The reason why we can offer a varied stock in the midst of the present shortage is *not* that we cannot sell, but that we **KNOW HOW AND WHERE TO BUY**. In ordering, a second or even a third choice should be given, as it is impossible in these days to keep any list up to date. Remember also the three salient terms of our dealing:

1. A three days' free trial, your money back in full at the end if not satisfied.
2. A three weeks' option of exchange. Your machine taken back at the full price paid within three weeks of purchase, for anything else from stock, or any new machine.
3. A three months' guarantee, the same guarantee that the makers give.
